

Name = Vaish Horte

Sub = Data Structure

Data structure is a representation  
of logical relationships between individual  
elements of data.

### Classification of Data Structure:

#### Data Structure

##### Primitive Data Structure

- Integer
- Float
- Character
- Pointer

##### Non Primitive Data

- |   |  |
|---|--|
| Linear  | Non-linear   |
| <ul style="list-style-type: none"><li>1) Array</li><li>2) Stack</li><li>3) Queue</li><li>4) linked-list</li></ul> | <ul style="list-style-type: none"><li>1) Graphs</li><li>2) Trees</li></ul> |

Primitive data → It is a data type which is provided by a programming language as a basic building block.

Non primitive data structures are the type which is created or derived by using primitive data types.

## Sub → Data Structure

### ★ Data Structure :-

⇒ A data structure is a particular way of organizing data in a computer so that it can be used effectively.

Two main words are there for Data structure which is **Organizing & Efficiency**.

• Data can be defined as an elementary value or the collection of values, for example, student's name & its id are the data about the student.

⇒ There are various operations that can be performed on Data structures. These are:

① Creation = Creating a data structure according to the requirement.

② Insertion = Inserting values into data structure. There can be three ways to insert elements into data structure: at the beginning, at the end & at the desired location.

Simply insertion means to add the new values into data structures.

③ Traversing = Visiting each element of the data structure at least once.

(4)

Search : searching of an element in the given no. of elements. It can be searched in two ways:

- Linear search : simplest way of searching an element.
- Binary search : it works on divide & conquer rule.

(5)

Sorting : arranging data को arrange करना  
एक particular order like  
ascending to descending.

To arrange the data in a particular order

(6)

Merging : combine the data items of  
two sorted file into a single  
file is known as merging.

Simply किसी दो data की 2 files को पाये  
हुए file को combine करते ही mix करना उसे  
मिश्निंग कहते हैं।

(7)

Updation : old data को new  
data के साथ replace करना ही  
हो जाता है तो update (add) the new things to  
that data.

(8)

Deleting : Deleting the undesired  
value from the data structure

## \* Characteristics of Data Structures:

- i) Linear Or non-linear = It describes whether the data items are arranged in sequential order, such as with an array, such as with a graph.  
non-linear is in multiple order.
- ii) Homogeneous = It describes whether all the data items ~~are~~ are in a given repository of the same type. One e.g. is a collection of elements in an array, or of various types, such as an abstract data type.

## Data Structure

Linear Data Structure	Non-linear data structure
Array	
Stack	
Queue	
Linked-list	
	Graphs
	Trees

### \* Stack :

- the data structure follows the rule of LIFO (last in first out) where the data last added element is removed first.  
push operation is used for adding an element of data on a stack & the pop operation is used for deleting the data from the stack from the same end.

3

Stack में एक ही जगह से elements को Push (insert) किया & Pop (deletion) किया जाता है।  
Simply it means Stack has only one end for deletion & insertion both.

Imp ☆

और जब empty हो stack ने संगर ही उसमें से elements को remove करते की तरफ करते ने भी underflowed कोहलादारा।

★

Same way में stack की maximum limit से ब्याला संगर से elements को push (insert) करतारामों ने उस time overflow की situation form भी पताकी।

o

Queue :- Queue is the linear data structure which follows the rules of FIFO which means First in first out.

इसमें simply ut elements को भी पहले insert करतारामों वही element भी पहले ही remove होता।

Queue ~~stack~~ में 2 ends होते हैं इक जगह से element (insert) enter होता & निसे enqueue होते हैं और दूसरी जगह से element exit (remove) होता & निसे dequeue होता है।

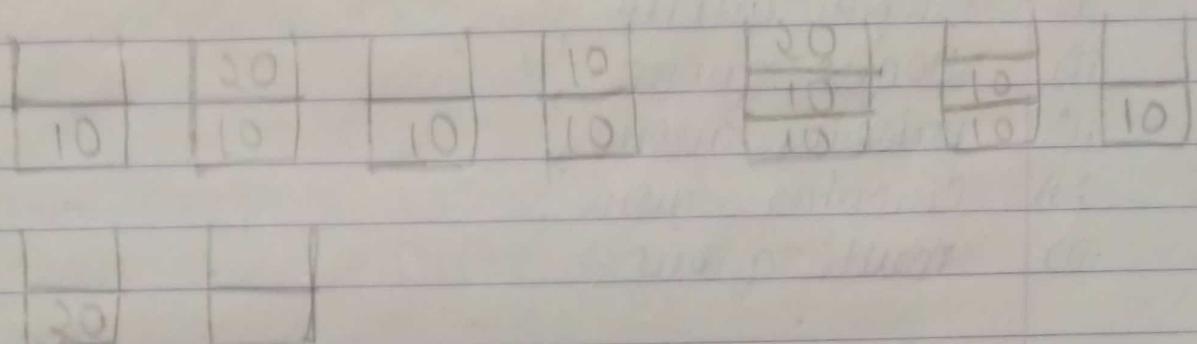

(Stack based question)

Ques The following sequence of operation is performed on a stack.

push(10), push(20), pop, push(10), push(20),  
pop, pop, pop, push(20), pop.

What will the sequence of popped value?

soln

Thus the sequence of Pop is 20, 20, 10, 10, 20

\*ii Queue = Queue is the linear data structure which follows the rules of FIFO which simply means First in First Out.  
इसको simply समझ आ रहा है कि जब element enter होता वही remove की पड़ते ही होता।

Note the element which insert firstly it remove firstly also.

Queue में 2 सिलगे ends होते हैं उन्हें end of insertion कहता है यहाँ कि elements add होते हैं और जिस दूसरे Enqueue कहते हैं उन्हें (to) भी कहते हैं उन्हें end से deletion (removing) होता है कि elements जब दूसरे Dequeue कहते हैं।

Also, if element inserted at the end we called it rear end & at the end from where the element get removed that end we called as front end.

There are 5 types of Queue :-

- i) Simple queue,
- ii) Deque queue,
- iii) Priority queue,
- iv) Circular queue,
- v) multi queue.

→ Deque queue :-

- It means double ended queue, here in this we can insertion & deletion from both the ends (include rear & front).

Now in this there are two types of Deque queue :

- i) Input restriction → In this, insertion can be done from only one end & deletion can be both the ends.
- ii) Output restriction → In this, insertion can be done from both the sides but deletion can be done from only one end.

Easy way:

### \* Operations on Data Structure:

- 1) Insertion = To add (insert) the new element in the Data Structure.
- 2) Deletion = To remove an element from the data structure.
- 3) Searching = to find (search an element in the Data Structure).
- 4) Traversing = To visit the data element atleast one time.
- 5) Sorting = to arrange the element in some logical order like ~~for~~ from ascending to descending or from descending to ascending.
- 6) Merging = combining two data structures of same type to form a new data structure of same type.

Simp

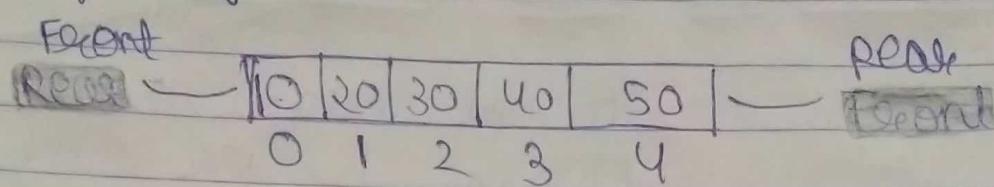

Types of Queue :

- ① Simple Queue = In simple queue, we can perform enqueue (insertion) at rear end & deque (deletion) at front end which follow the rule FIFO (First in first out). Elements will be enqueued at front and element will be dequeued at rear.

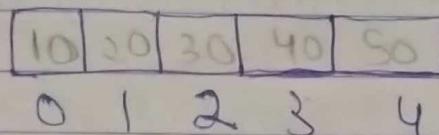

Simple E.g like :-

simple जिस element को हम पहले enter करताएंगे वही पहले remove होता।

In this simple queue, insertion can be done from rear & deletion can be done from front.

→ अब एक queue के structures में कोई भी element ना हो null की situation हो तो  
 उस time हम  $front = 0$   $front = -1$  &  
 $rear = -1$  लगाएँ :

in case of no element present, place we  
can take a Front = rear = -1

Now if i have to apply enqueue the element :

$$\begin{aligned} \text{scale} &= \text{year} + 1 \\ &= -1 + 1 \\ &= 0 \end{aligned}$$

Now, another if I have to enqueue the  
another element:

$$\begin{aligned} \text{rear} &= \text{rear} + 1 \\ &= 0 + 1 \\ &= 1 \end{aligned}$$

Next element will be in 1<sup>st</sup> position

∴ same concept Front का :-

जब First element insert हो तो First  
remove (dequeue) होता :-

$$\begin{aligned} \text{front} &= \text{front} + 1 \\ &= -1 + 1 \\ &= 0 \end{aligned}$$

जब null या तो Front की value -1 हो  
that's why -1 लिए the deletion करते हैं

(ii) Circular Queue :- In circular position queue, last position is connected to first position to make circular & the main advantage of circular queue is the utilization of memory.

As, circular queue जो होता है को circular form में होता है means इस ग्राफ संकेत कि उसका last point जो होता है first point से connect होता है circle में सभी interlinked होते हैं क्योंकि वे obvious भी होते हैं last position पर element insert करने के बाद काप्ती standing point के element insert कर सकते हैं निकले memory waste नहीं जाता है सभी बड़े memory

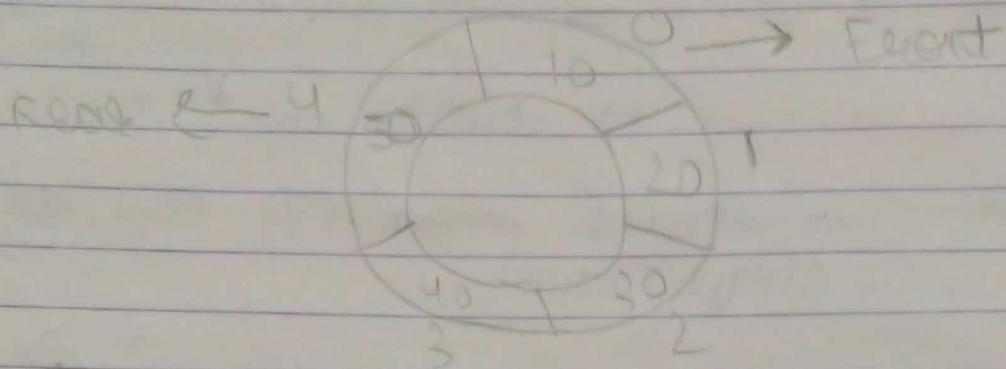

for null queue :

$$\text{Front} = -1$$

$$\text{Rear} = -1$$

empty still we get element instead of error  
So we can say that in circular queue  
there is utilization of memory means,  
it can't be waste.

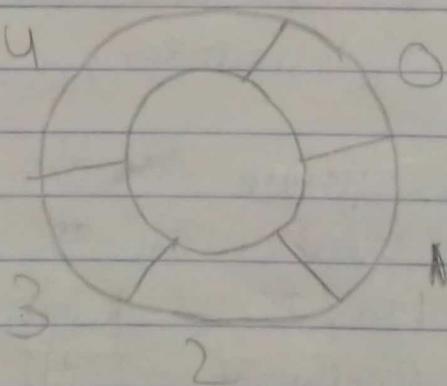

For Enqueue (Insertion) : From Rear end

$$\text{Rear} = (\text{Rear} + 1) \% \text{ Maximum size}$$

sol<sup>n</sup>) Like we will take one example as  
the circular queue is empty & we  
have to enqueue (insert) one element  
which is 10 & its maximum size is 5

Sol<sup>n</sup>)

As we have to insert 10 so before this  
it is null queue & we know that  
at the time of empty queue the

value of Front = rear = -1

Formula for enqueue the element from rear end for circular queue is:

$$\begin{aligned}\text{rear} &= (\text{rear} + 1) \% \text{ Maximum size} \\ &= -(+1 \% 5 \\ &= 0 \% 5 \\ &= 0\end{aligned}$$

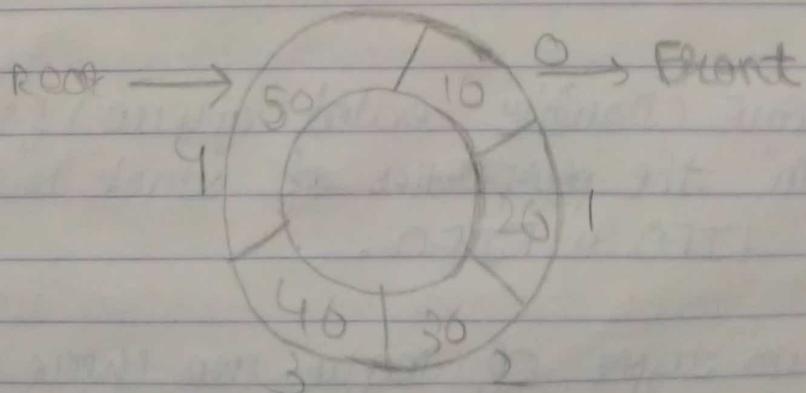

thus, the element 10 will be insert in 0<sup>th</sup> position.

⇒ Now, same for deque (deleting) the element from front end:

$$\text{front} = (\text{front} + 1) \% \text{ Maximum size}$$

ques) As in the circular queue there are 5 elements whose size is full namely 10, 20, 30, 40, 50 & we have to deque the element.

Sol:

→ अबके पांचवीं element insert होता है तो  
अब विनाय की रुपरेखा (FIFO) लगती है :

formula for front is :

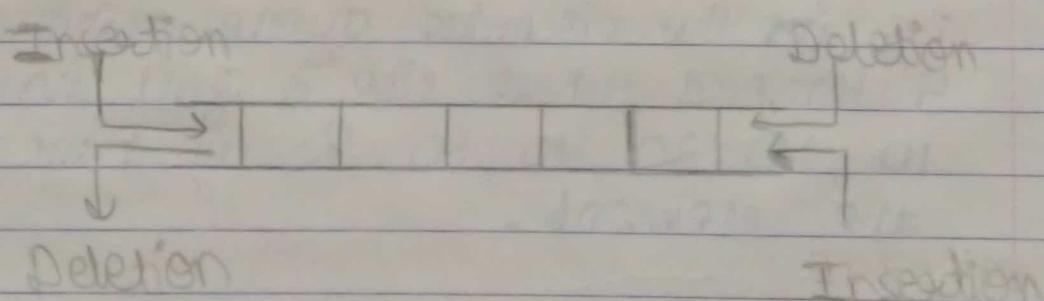

$$\begin{aligned}\text{Front} &= (\text{Front} + 1) \% \text{ maximum size} \\ &= -1 + 1 \% 5 \\ &= 0 \% 5 \\ &= 0^{\text{th}}\end{aligned}$$

thus,  $0^{\text{th}}$  position का 10 element Front  
होता है तो remove करता है।

iii)

Deque (Double ended queue) :

→ In Double ended queue, insertion (enqueue)  
& deletion (dequeue) are allowed from  
both the rear & front end.

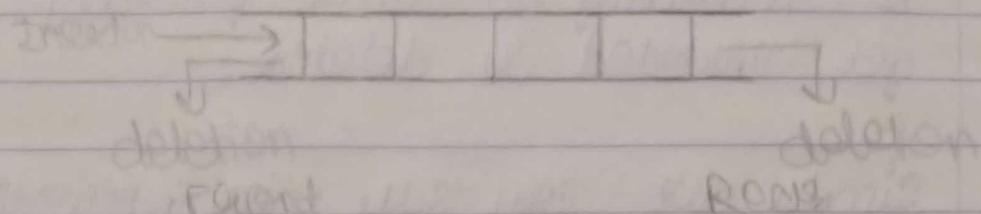

Deque (Double ended queue) follows  
both the properties of Stack & Queue which  
is LIFO & FIFO.

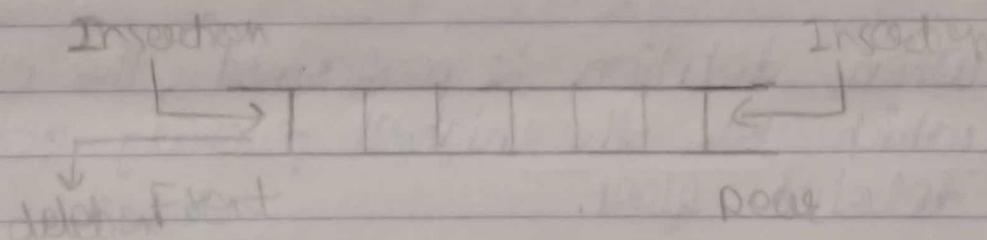

Two types of Deque are there :

- ① Input restriction = In input restriction, insertion can be done from only one end & deletion can be done from both the ends.

- ② Output restriction = In output restriction, insertion can be done from both the ends but deletion (dequeue) can be done from only one end.

### \* Operations which we perform on deque :

- insert at front.
- delete from front.
- insert at rear.
- delete from rear.

\* 3) Priority Queue = A priority queue is a linear data structure in which every element has some priority & according to their priority that element get inserted & deleted.

Simply we can say that in priority queue elements वह हैं जो priority के फिराब से insert होते हैं तो priority के फिराब से ही delete होते हैं :

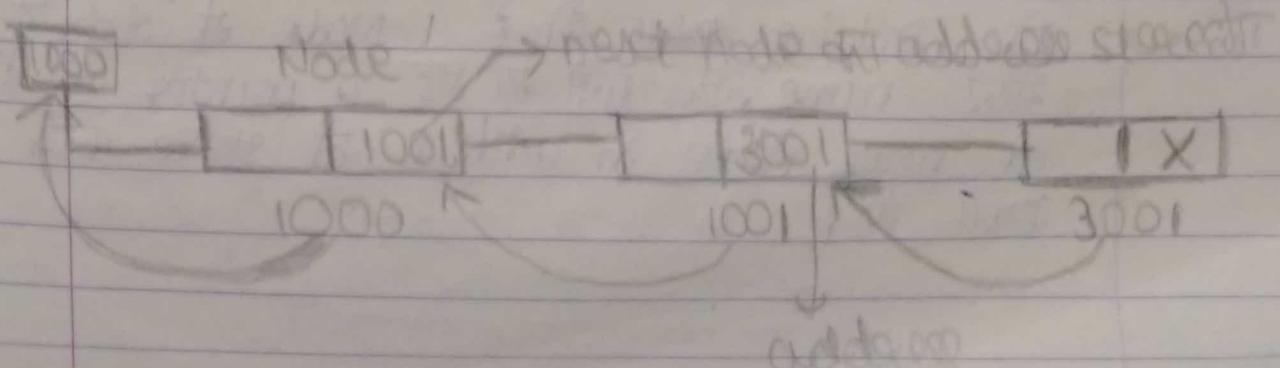

- It processes by the following rule :-
  - ⇒ When deletion is performed, the element which has the highest priority get deleted first.
  - ⇒ When insertion is performed, the new element is placed or enter on the basis of its property.
  - ⇒ When the elements are of same level priority then the element which enter first that get inserted or deleted first.
- Priority Queue are two types :
  - i) Ascending = Insertion is random but deletion can be done from smallest element which has lower priority.

② Descending → insertion is random but deletion can be done from greater element which has higher priority.

## linked List

- \* Linked List = A linked list is a linear data structure. It is a collection of data elements called node. Every Node is the place where we store data item. Every node has two part one is information & second is pointer or address where we store the address of next elements or next node which link next element in the list.
- \* Null means it's an invalid address.
- \* Every node has two part, first one is information which includes name, address &c. & second part is pointer field & it stores next node's address.
- \* Pointer field में एक next node का address रखता है।
- \* Pointer field में next node का address रखना means maintain means रखना है।

- In this pointer stores the address of the next node.
- One most important thing about linked list is that:

In linked list the elements are not stored at contiguous memory locations. The element elements in a linked list are linked using pointers.

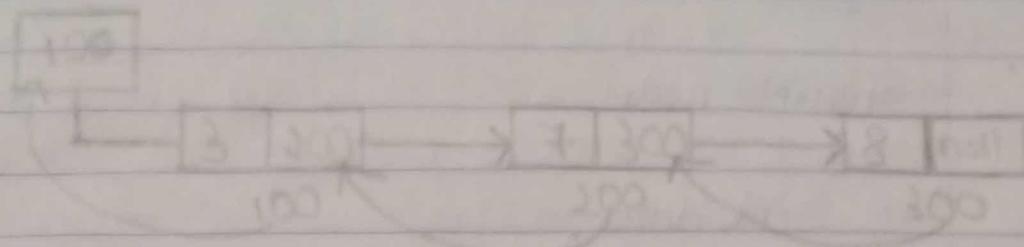

- Types of Linked List:
- ★ • Singly Linked List:

→ In singly linked list, every node contains some data & a pointer to the next node of the same data type. Here the node contains a pointer which stores the address of the next node in the sequence. A single linked list allows traversal of data only in one way.

• यह एक node जिसे अंदर data & pointer को contains करता है। Node के data के अंदर name, etc. जैसी मात्रे & pointer जो कि को next node के address को store करके रखता है।

e.g. →

### Implementation:

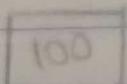

struct node

{

```
int data;  
struct node * next;  
};
```

### \* Doubly linked list

- In doubly linked list, every node contains data & pointer one & pointer two or 2 pointers in which left side pointer stores the address of previous node while right side pointer stores the address of next node. This would enable us to traverse the list in the backward direction & upward direction.

## Algorithm :-

struct node

{

int data;

struct node \* next;

struct node \* previous;

}

## Circular linked list :-

- In Circular linked list, the last node is connected to the first node means in this the pointer of the last node contains or stores the address of the first node. Simply we can say that a circular linked list has no beginning & no end.

Head

100 | 15 |

next | 200 |

## Double Circular linked list :-

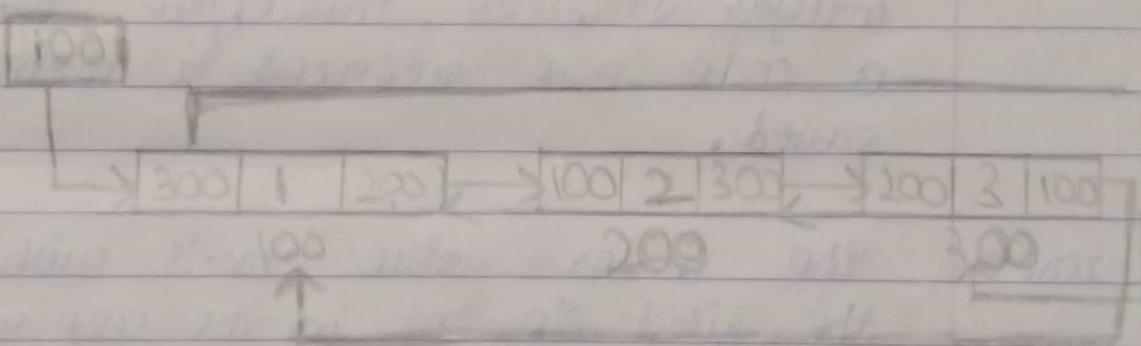

- In double circular linked list ~~every~~ some here the last node is connected to the first node & here every node

contains or stores the data & two pointers in which left side or we can say that previous node, so left side pointer stores the address of previous node & right side pointer stores the address of next node as here the nodes are in circular form so last node is directly connected to the first node in the same way, the pointers of the last node stores the address of first node.

e.g. :-

### \* Array :

⇒ Array is the collection of similar kinds of data types. यह एक निश्चय की collection होता है जोकि वह कोई निश्चय के data types का जोड़ सकता है जैसे int में ही इन्टरीज़ भिन्न अंकों को जोड़ सकता है और float में ही float भिन्न अंकों को जोड़ सकता है।

• The array is a type of data structure that stores elements of the same data type.

Array is the most basic & fundamental data structures. Data stored in each position of an array is given a positive value called the index of the element. The index helps in identifying the locations of the elements in an array.

- If supposedly we have to store some data i.e. the price of ten cars, then we can create a structure of an array & store all the integers together. This doesn't need creating ten separate integer variables. Therefore the lines in a code are reduced & memory is saved.

IMP :-

the index value starts with 0 for the first element in the case of an array

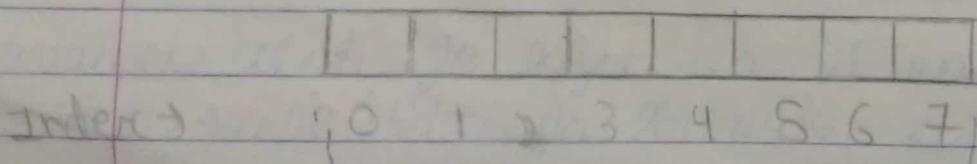

Array ~~is~~ ~~are~~ ~~get~~ ~~value~~ elements at ~~for~~ index values ~~then~~ 0 it start ~~at~~.

- Declaration of an array:

Data Type array Name [array size];

e.g.:

int num [8];

$$n = 8$$

→ An array is given:

2	4	3	7	6
0	1	2	3	4

→ Here upperbound = 4 (which is highest index)  
↓ lowerbound = 0 (which is lower index)

$$\begin{aligned}\text{Size of array} &= (\text{Upperbound} - \text{Lowerbound}) + 1 \\ &= (4 - 0) + 1 \\ \Rightarrow 4 + 1 &= 5\end{aligned}$$

- \* In array, we can store many values in one variable.
- \* Array is a collection of more than one elements & the condition is that the data type of those elements should be similar.

Ans How the elements of the data is stored in the memory in array?

Ans All the elements are stored in consecutive continuous manner, one after another.

\* Simple & Point to Point definition of an Array:

→ Array is a fixed size sequenced collection of data items of same data type.

3 How to declare an array:

[data type array name [array size];]

Simple Flowchart of defining  
an Array

→ What is Array?

Array is the collection of similar  
kind of data types (like int - int,  
float - float, char - char).

How to declare an Array?

[data type array name [array size];

e.g. → int a [5]

↓      ↓      ↓  
data    array    array  
type    name    size

Memory allocations → contiguous  
form में memory allocate होता है यहाँ में  
एक के बाएँ एक form में।

4. Array के size के subscript के  
size कीजा जाता है।

subscript E]

ये subscript अलगाता है।

## Initialization of an array

first type = `int a[5] = { 10, 20, 30, 40, 50 }`

second type = `int a[ ] = { 10, 20, 30 }`

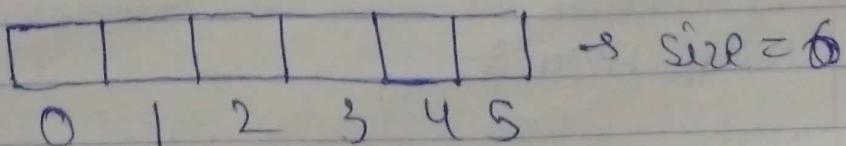

इसका simply मतलब है कि जो भी इन्हें array को initialize किया है उसका निम्ने जी elements होंगे तभी उन्हें elements array के size के रूप में आ पाएंगे, ऐसे :

`int a[ ] = { 10, 20, 30 }`

↓

अब इसमें 3 values initialize कराए हैं तो उस array का size भी 3 आ पाएगा।

- Some common points of array which will define array in every language
- An array is the collection of similar kind of data type.
- the first element in the array is numbered 0 so the last element will be 1 less than the size of array. Let's take ex. : if the size of an array is 6 then its index value starts from 0.

thus the last element is 5, i.e. then 6.

3) Array is declared with subscript [ ] so it is also called subscripted variable.

Subscript = [ ]

4) Array is declared with : ~~Subscript~~ data type array name [array size];

5) Array is always stored in contiguous memory allocation. (1st to nth)

6) Array initialization is done with { } brackets.

### One Dimensional Array

→ One-Dimensional array is one in which only one-subscript [ ] specification is needed to specify a particular element of the array.

Simply one-dimensional array के एक राहे में  
subscript [ ] use करते हैं, ~~जो~~ ~~जो~~ ~~जो~~ elements

Declaration of an array in 1 dimensional

Data Type Array name [Array size];

- Now Here :-

→ Data type = Data type is the type of element to be stored in the array.

i) One dimensional array → In this array only one subscript, either in form of rows or columns used to define the elements of arrays.

• Initializing one-dimensional array → / assigning

→ Data type array name [size] = { values }

For e.g. for int:

int num [10] = {1, 2, 3, 4, 5, 6, 7, 8, 9, 10};  
char char [5] = {'A', 'B', 'C', 'D', 'E'}  
arr

ii) Multi-Dimensional array → Multi-Dimensional arrays use more than one subscript to describe the array elements. Its types:

i) Two Dimensional array → It uses two subscript, one subscript to represent row value & second subscript to represent column value. It mainly use for matrix representing.

Declaration of two Dimensional array:

Data type array name [row] [column];  
[size]

Ex: int num[3][2];

★ Initialization of 2-D array:

Data type array name [rows][columns]  
= {value}

Ex: int num[3][2] = {1, 2, 3, 4, 5, 6}

case 1: int num[ ] [ ] = {1, 2, 3, 4, 5, 6}

case 2: में लम्बे कह सकते हैं कि अगर  
size दिया है तो value initialize  
करने के लिए वाले values के लियाँ जैसे  
वर्ष column के store करते हैं।

Q) Ex:

0	0	1
1	3	4
2	5	6

$$(0,0) = 1$$

$$(0,1) = 2$$

$$(1,0) = 3$$

$$(1,1) = 4$$

$$(2,0) = 5$$

$$(2,1) = 6$$

★ Now we will see one-one program each  
for 1-D array & 2-D array.

→ some basic points:

In C language :

# is defined as pre processor  
<stdio.h> is the header file & stdio is stands for standard input output & it includes the function printf & scanf.

& <conio.h> is also the header file where conio is stands for console input output & it includes the function clrscr(), getch().

Ques → Write a C program to make the program of one dimensional array.

```
#include <stdio.h>
int main(){
    int a[6]; int i;
    printf("Enter the Array elements");
    for (i=0; i<6; i++){
        scanf("%d\n", &a[i]);
    }
    printf("The entered Array is");
    for (i=0; i<6; i++){
        printf("%d\n", a[i]);
    }
    return 0;
}
```

\* Tree is a non linear DS which shows parent child relationship among the nodes it organizes data in hierarchical manner.

Page No. \_\_\_\_\_

Date \_\_\_\_\_

Tree  $\rightarrow$  Non-linear DS

\* Trees :

- A tree is a non-linear hierarchical data structure that consists of nodes connected by edges.
- A tree is a hierarchical data structure defined as a collection of nodes which are linked or connected through edges.

For e.g. :-

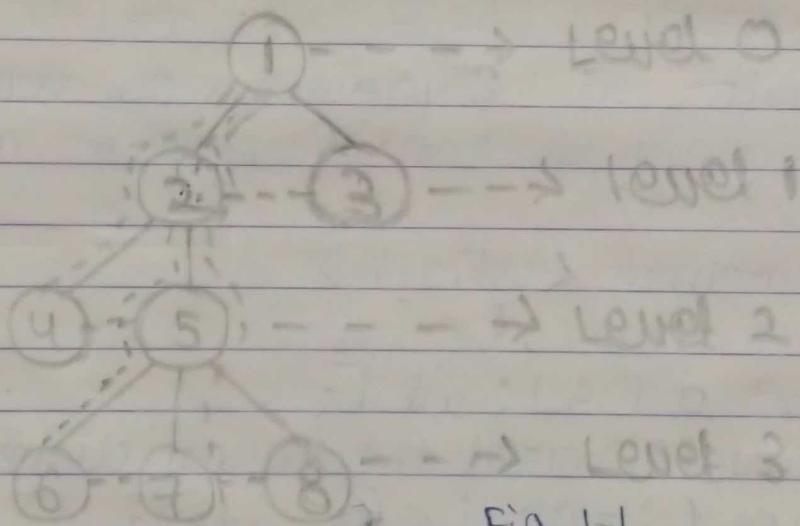

Fig. 1.1

↑ This is a tree

- Root node = The highest or top most node of a tree & the node which don't have any parent node called as root node.
- Now, what is node ?

data

Ans In the tree, each elements consists of stores some information in it which is referred to as nodes.

- Sibling :- Siblings are the children of the same parent or we can say that if the parent has 2 or more than 2 nodes then these nodes are the siblings of each other.
- Degree of node :- degree of node is the no. of children of that node.
- Degree of tree :- Maximum degree among all the nodes. (जिसकी राकर्ता ज्यादा डिग्री होती है। जिस नोड की Highest / maximum degree होती है वही डिग्री of tree होती है।)

### ★ leaf node or terminal node :-

⇒ The node which do not have any child node or the degree of that node is 0 is called as leaf node or terminal node.

### ★ Non-Terminal nodes or internal nodes :-

⇒ The node which has atleast one child node is the degree of any node be atleast 1 or more than 0, that node is called as Non-terminal / internal nodes.

★ Ancestor : Any predecessor node on the path from root of that node.

For e.g. in the Fig. 1.1

ancestor of 7 is = 5, 2, 1

ancestor of 6 is = 5, 1, 1

ancestor of 4 is = 2, 1

★ Descendant : Any successor node on the path from that node to leaf or terminal node is called descendant.

For e.g. in the Fig 1.1 =

descendant of 2 is = 5, 6, 7, 8, 4

descendant of 5 is = 6, 7, 8

★ Depth of node : length of path from root to that node.

★ Height of node : no. of edges in the longest path from that node to a leaf node.

★ Level of edge node : It is the no. of edges connected to the nodes.

From fig. 1.1, level of 2 is 1 & height of 3 is 1

Height of node = Level of node

- ★ path = The way from source node to destination node ~~for~~ through consecutive edges.
- ★ Forest = set of disjoint tree
- ★ Parent node = Predecessor node of the ~~same~~ ~~parent~~ any node.
- ★ child node = ~~for~~ <sup>successor node /</sup> descendant node of any node.

## Graphs

→ Graph is the collection of vertices (node) & edges where edges work to link the one to connect the vertices (two vertices). (Edges is the set of vertices)

Simply we will take one example :

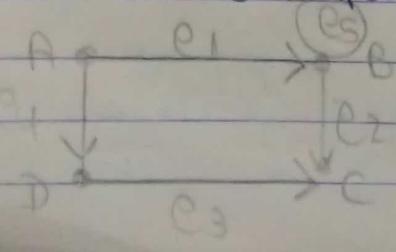

अगर हम एक city से अभी दूसरे city में  
जाना है तो उन cities के बीच की ओर सारे  
cities आएंगे तो वह city मारी nodes/vertices  
के जाएंगे & उनके बीच का distance का path  
हमारी edges के पास ही।

Like if we are going from one city  
to another city then in b/w them  
these are the cities so here the cities  
are the vertices or we can say that nodes  
& the edge distance b/w them or the  
path are the edges.

- Types of Graphs :

(Digraph)

- i) Directed Graph = Simply जिसमें ही direction  
को show करते हैं with the help of arrows.  
In this all the edges are directed from  
one vertex to another.

For example, in ABCD  
digraph there are 4 vertices  
A to B & B to A etc  
जबकि direction की  
प्राप्ति,

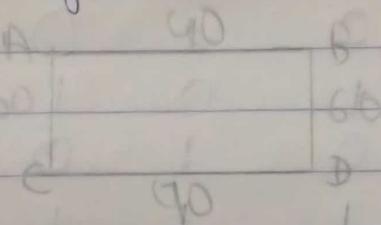

→ Degree = No. of edges connect to that vertices.

→ Adjacent = which are connected by same edge

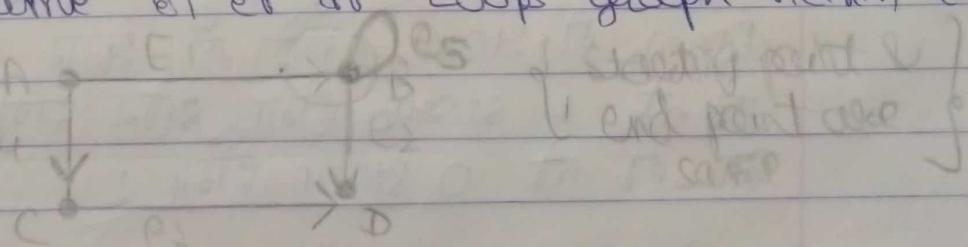

(ii) Undirected graph = जिसमें edges नहीं हैं  
but its directions show नहीं की हैं।

Undirected graphs have edges but they do not have any directions but all the edges are bidirectional.

(iii) Weighted graph = Simply it means वज़ह है,  
जैसे edge को weighted value assign करते हैं।  
It refers to where weights are assigned to each edge.

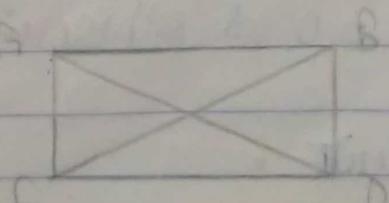

(iv) Loops = जिसका starting point & end point same है एवं इसका loops graph मानता है।

## A Graph & its Representation :

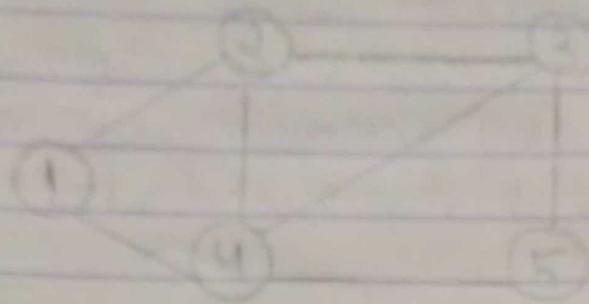

• Complete Graph : In complete graph every vertex node is adjacent to every other node (vertices).

$$\text{Here } n \text{ no. of vertices } \& \text{ edges} = \frac{n(n-1)}{2}$$

## ① Adjacency matrix :-

Here n is used for row & column like

$$\begin{array}{c|ccccc}
 & & j \rightarrow & & & \\
 i \downarrow & & 1 & 2 & 3 & 4 & 5 \\
 \hline
 1 & 0 & 1 & 0 & 1 & 0 \\
 2 & 1 & 0 & 1 & 1 & 0 \\
 3 & 0 & 1 & 0 & 1 & 1 \\
 4 & 1 & 1 & 1 & 0 & 1 \\
 5 & 0 & 0 & 1 & 1 & 0
 \end{array} \quad 5 \times 5$$

यहाँ पर  $i$  &  $j$  में values bits (binary) के form में store होती हैं अगर  $i, j$  दोनों adjacent होते हैं तो 1 stored होगा और अगर  $i, j$  दो adjacent न होते हैं तो 0 stored होगा।

It is a matrix  $A[n][n]$  where  $n$  is no. of vertices :-

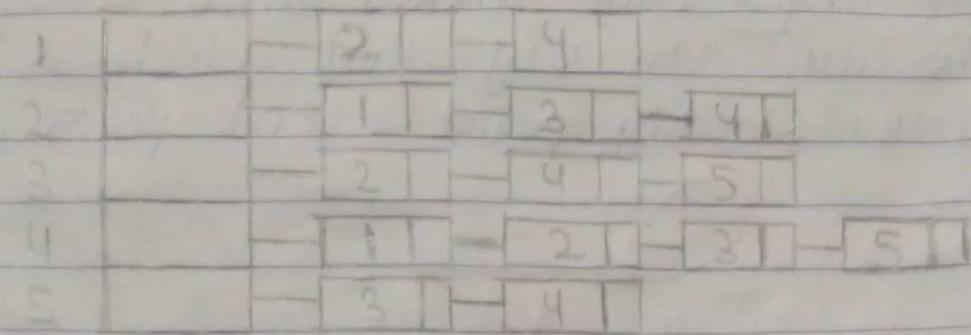

$$\left\{
 \begin{array}{l}
 a[i][j] = 1 \rightarrow \text{if } i \& j \text{ are adjacent} \\
 = 0 \rightarrow \text{otherwise not adjacent}
 \end{array}
 \right.$$

In this matrix :-

$$\Theta(n^2)$$

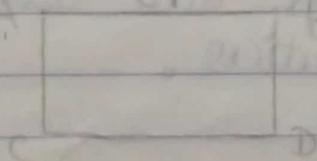

## ② Adjacency list :-

By this :

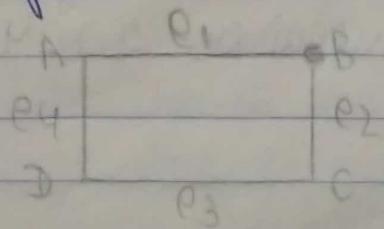

$$\mathcal{O}(n+2e)$$

\* i) Adjacent vertex = If two vertices are joined by the same edge they are called adjacent vertex.

So, here two vertex A & B are joined by the same edge e.

\* ii) Adjacent edge = If two edges are meet / lie on the same vertex, they are called adjacent edge.

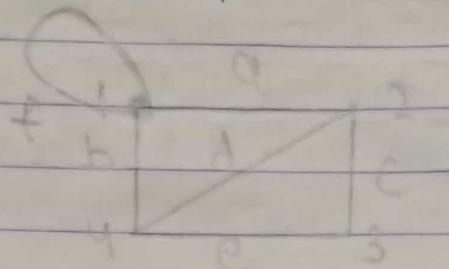

Here two edges e1 & e2 are incident

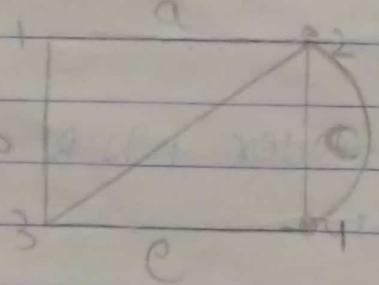

on the same vertex B.

- iii) Self loop :- Edge having same vertices ( $v_i, v_i$ )  
also we can say that which is having  
same starting point & end point.

Here, f is starting from 1 & end on 1 which means start & end from the same point.

- iv) Parallel edges = These are also called multiple edges, in an undirected graph, two or more edges that are incident to the same two vertices.

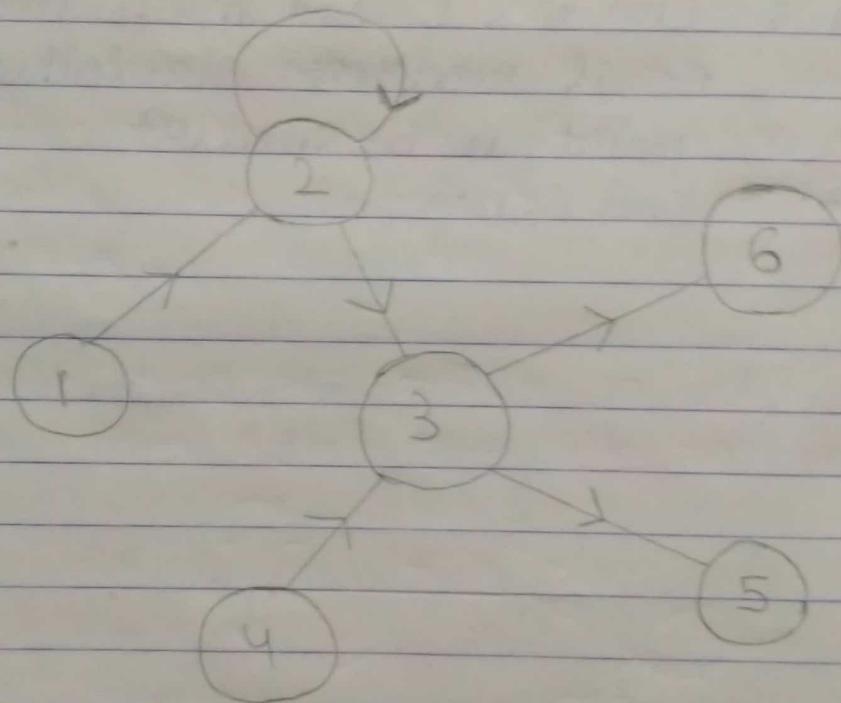

So, here, two (2) &

So, here c & d two edges are incident to the same vertices 2 & 4.

## Remaining Graphs

- Adjacency matrix of given graph for directed / digraph.

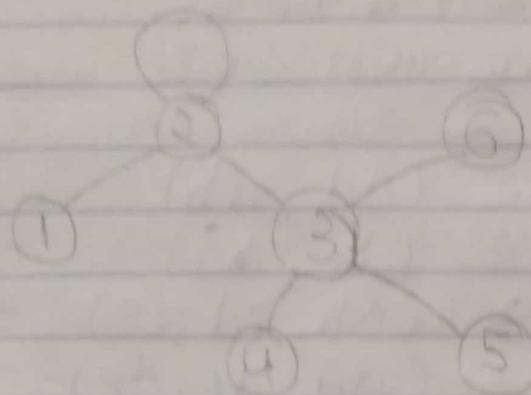

Here we will store the value in the form of bits (0 & 1) if i & j are adjacent then 1 will be stored otherwise 0 if not adjacent:

$j \rightarrow$	1	2	3	4	5	6
1	0	1	0	0	0	0
2	0	1	1	0	0	0
3	0	0	0	0	1	1
4	0	0	1	0	0	0
5	0	0	0	0	0	0
6	0	0	0	0	0	0

Now, adjacency matrix of a given graph  
for undirected graph.

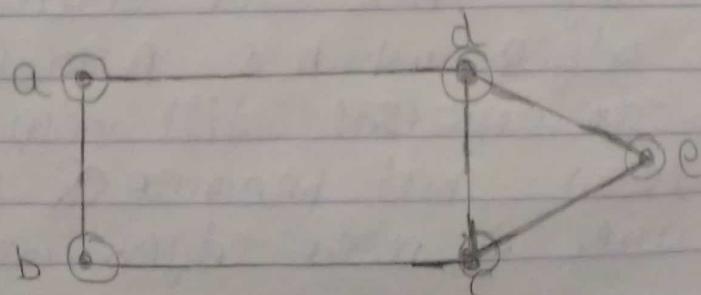

Now here there were no directions so  
we can take bidirectional graph?

$j \rightarrow$	1	2	3	4	5	6
1	0	1	0	0	0	0
2	1	1	1	0	0	0
3	0	1	0	1	1	1
4	0	0	1	0	0	0
5	0	0	1	0	0	0
6	0	0	1	0	0	0

Now, we will see the degree of the  
graph :

- \*  $\text{Degree} \rightarrow$  No. of edges which are connected / incident to that vertex.

→ Now, here from the vertices in there were two edges are connected which is from a to d & a to b.  
So, the degree will be:

$$\text{degree}(a) = 2 \text{ (ad, ab)}$$

$$\text{degree}(b) = 2 \text{ (bc, ba)}$$

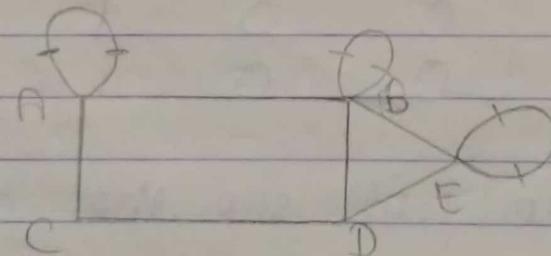

$$\text{degree}(c) = 3 \text{ (cb, cd, ce)}$$

$$\text{degree}(d) = 3 \text{ (da, dc, de)}$$

$$\text{degree}(e) = 2 \text{ (ed, ec)}$$

Note → If there were no edges connected to that vertex then the degree of that vertex be 0 which is called as isolated vertex.

Now, if there were a self loop in the graph then the degree will change:

Here the self loop contains 2 degree (2 edges) in itself:

We can say that the vertex already has two edges which is A to B & B to C so we can say that till now the degree of A is 2, but because of self loop there will 2 more edges increased.

$$\therefore \begin{aligned}\text{degree (A)} &= 4 \\ \text{degree (B)} &= 5 \\ \text{degree (C)} &= 2 \\ \text{degree (D)} &= 3 \\ \text{degree (E)} &= 4\end{aligned}$$

Now, we will study the indegree & outdegree in the directed graph:

IMP →

Note that: in degree & outdegree is only in the directed graph because of the directed graph showing directions:

Firstly we will define indegree as:

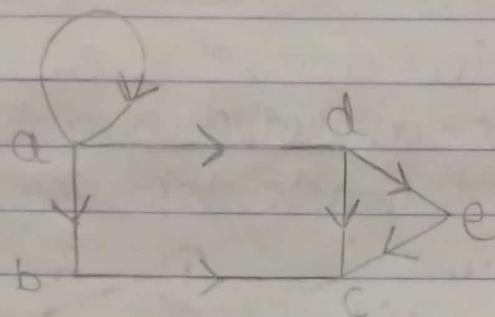

- 1) Indegree = No. of edges which are also connected or incident on that vertex which are only coming toward in the direction of that vertex, which we called as indegree.
  - 2) Outdegree = No. of edges which are connected or incident on that vertex which are going away from that vertex, we called as outdegree.
- Now, here we will define these degrees with the help of example:

Directed graph:

Here one more important thing is that if the self loop is made on any vertex then it would be considered as 1 edge is coming towards that vertex & 1 edge is going away from that vertex:

Directed graph :

Here :

$$\text{indegree}(a) = 1$$

$$\text{outdegree}(a) = 3$$

$$\text{indegree}(b) = 1$$

$$\text{outdegree}(b) = 1$$

$$\text{indegree}(c) = 3$$

$$\text{outdegree}(c) = 0$$

$$\text{indegree}(d) = 1$$

$$\text{outdegree}(d) = 2$$

$$\text{indegree}(e) = 1$$

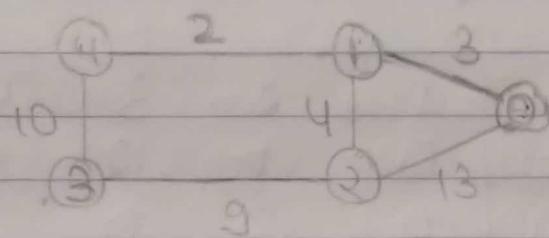

$$\text{outdegree}(e) = 1$$

New topic :-  
Undirectional Weighted graph  
/ Bi-directional graph weighted  
graph in Adjacent list

⇒ Undirectional weighted graph in Adjacency list : In this we will assign the weight :

First we will see undirectional weighed graph in adjacency matrix :

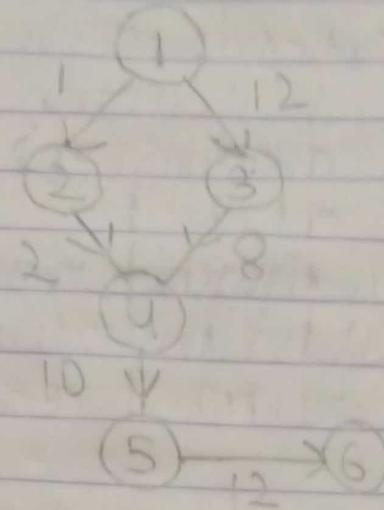

⇒ We will see its representation :

$$\begin{matrix} & \begin{matrix} 0 & 1 & 2 & 3 & 4 \end{matrix} \\ \begin{matrix} 0 \\ 1 \\ 2 \\ 3 \\ 4 \end{matrix} & \left[ \begin{matrix} 0 & 3 & 13 & 0 & 0 \\ 3 & 0 & 4 & 0 & 2 \\ 13 & 4 & 0 & 9 & 0 \\ 0 & 0 & 9 & 0 & 10 \\ 0 & 2 & 0 & 10 & 0 \end{matrix} \right] \end{matrix}$$

(5x5)

Here we will assign the values of weight according to their adjacent edges.

\* Now, we will see the digraph weighted graph in adjacency matrix.

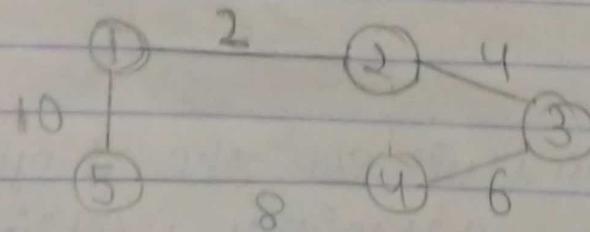

there are 6 vertex so matrix will be formed of  $6 \times 6$  (6 rows & 6 column)

	1	2	3	4	5	6	7
1	0	1	12	0	0	0	
2	0	0	0	2	0	0	
3	0	0	0	8	0	0	
4	0	0	0	0	10	0	
5	0	0	0	0	0	0	12
6	0	0	0	0	0	0	

(6x6)

- (ii) Undirected weighted graph in adjacency list : In the first pointer we will write the vertex & in second link we will write the value of weight we assign it

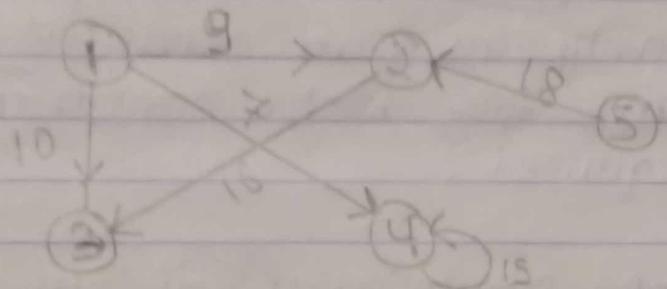

We will store in the form of linked list :-

1	7	2 2	5 10 X
2	6	1 2	3 4 X
3	4	2 4	4 6 X
4	3	3 6	5 8 X
5	1	1 10	4 8 X

\* Now for directional graph in adjacency list form :-

Here also we will store in the form of adjacency list :-

1		2 9	3 10	4 7 X
2		3 16 X		
3				
4		4 15 X		
5		2 18 X		

## Algorithm

⇒ Algorithm = It is the finite sequence of instructions which is used to solve a problem & step by step representation

⇒ Easiest definition :

- An algorithm is the sequence of the process / instruction or it is the collection of steps which shows the logic of the program with input & output.
- It is a set of steps to accomplish a task.

Ques: Why we need the algorithm?

Ans: we will understand why we need the algorithm by using an example: as if we have to construct the building firstly we have to design the map of that building means for better construction of building map is required.

In the same way if we have to make the program we have to design its algorithm (or set of instruction which we need to design the program) so we can say that "to design the better program algorithm is required."

## \* Difference b/w Algorithm & Program

### → \* Algorithm :

i) In algorithm we have to design the phase not to implement, we just have to design the phase in the page, notepad, wordpad etc. but we don't have to implement it on any ide's.

ii) We have to write these algorithm in our natural language like English, we don't have to maintain any syntax in it.

iii) Algorithm can be created by those person who should have the domain knowledge of that particular algorithm.

iv) We have to analyse that algorithm means we have to check it either we did any mistake or not then we can correct it.

### \* Program :

i) In program, we have to implement the phase in the ide's.

ii) We have to write the program by using proper syntax of that program & includes all the rules of that programming

# Flowcharts in algorithm

## divide conquer & combine

Page No.

Date

language.

- iii) We have to compile & run the programs or testing the program.

Ques How to write the algorithm :

- we have to do sum of two integers:

Algorithm :

Step 1 : Start

Step 2 : Input of a & b where  
a is 45 & b is 68

Step 3 : Sum = a+b

Step 4 : print the sum

Step 5 : Stop / End

- Now if we have to check that which no. is greater :

Algorithm :

Step 1 : Start

Step 2 : Enter a & b

Step 3 : if  $a > b$  then print that a  
is greater else print b is greater.

Step 4 : end

/ stop

\* Another way if we have to write the algorithm for checking which no. is greater.

Algorithm =

Step 1 : Start  
Step 2 : Read the a & b  
Step 3 : if  $a > b$  then go to step 4  
else goto step 5.  
Step 4 : print a is greater.  
Step 5 : print b is greater.  
Step 6 : Stop / end.

\$ Now algorithm to find the largest number in b/w them :

Algorithm =

Step 1 : Start  
Step 2 : Read a, b & c  
Step 3 : if  $a > b$  and  $a > c$  then print that a is largest.  
Step 4 : else if  $b > a$  and  $b > c$  then print that b is largest otherwise / else print c is largest.  
Step 5 : Stop / end.

Ques

We have to write the algorithm for finding the smallest number among them.

Algorithm :

Step 1 : Start

Step 2 : Read l, m & n

Step 3 : if  $l < m$  and  $l < n$  then print  
l is smallest

Step 4 : else if  $m < l$  and  $m < n$  then print  
m is smallest else / otherwise  
print n is smallest.

Step 5 : End / Stop

## Algorithm

- ⇒ An algorithm is the finite set of instructions which are used to solve the problem or the given task.
- ⇒ Step by step representation to solve the particular task.
- As, if we want to construct the building, firstly we have to design its map means with the proper planning then only we can construct any building it means for better construction map is required.

In the same way if we want to design the better program, algorithm is required, which is the infinite set of instructions which are eas. used to solve the program.

- ★ Here an algorithm can be specified using pseudo-code or flowcharts:
- Pseudo-code = It is a detailed description of an algorithm which is easier to understand & is expressed in the natural language (English).

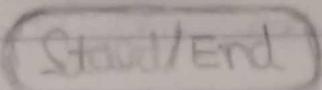

e.g. # Algorithm for sum of two numbers in the pseudo code form:

- ⇒ Step 1 : Start
- Step 2 : Input a & b
- Step 3 :  $c = a + b$
- Step 4 : Print c
- Step 5 : Stop / end

★ Flowcharts = It is the type of algorithm which is the pictorial or graphical representation with the help of graphical symbols which are used to solve the problem.

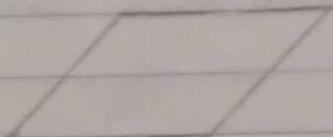

Some basic terminology which we have to understand are:

(i)

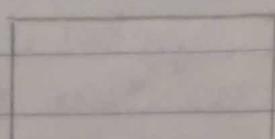

= Here oval shape is used to start & end the problem. It is also called as terminal.

(ii)

= Parallelogram symbol is used for input and output statements.

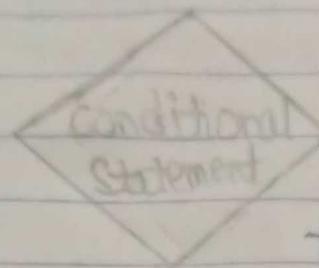

(iii)

= Rectangle is used to perform process which includes calculations, addition, subtraction etc., arithmetic

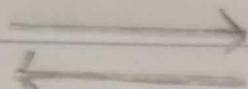

(iv)

Here diamond/schombus represent = a decision or conditional statements. It contains a level false statements. Here it includes two arrows, one is for true condition & second is for false condition.

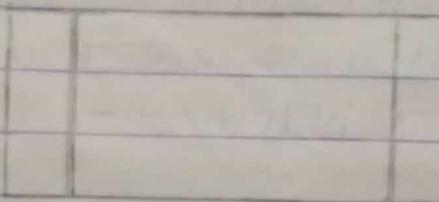

(v)

= Here Arrows represent the flow of control.

(vi)

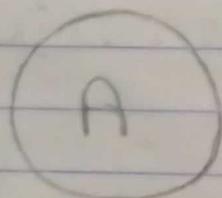

Predefined process symbol :

calculation करना  
प्रति त्रै बट प्रत्यु  
मि वेद से दी जा  
दिए रहों दिए  
करना अस्त्रांगी

Predefined process symbol is used to show the operation or process that has been already defined by another flowchart.

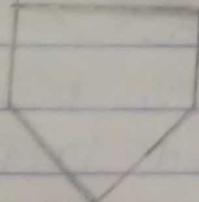

(vii)

This is on-page reference.

= This circle is also known as connector which indicates that the next (or previous) step is somewhere else situated.

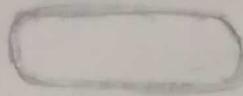

(viii)

This is off-page reference. It

= indicates that the flow continues on a matching symbol containing the same letter somewhere else on a different page.

Start & end can be :

both are allowed

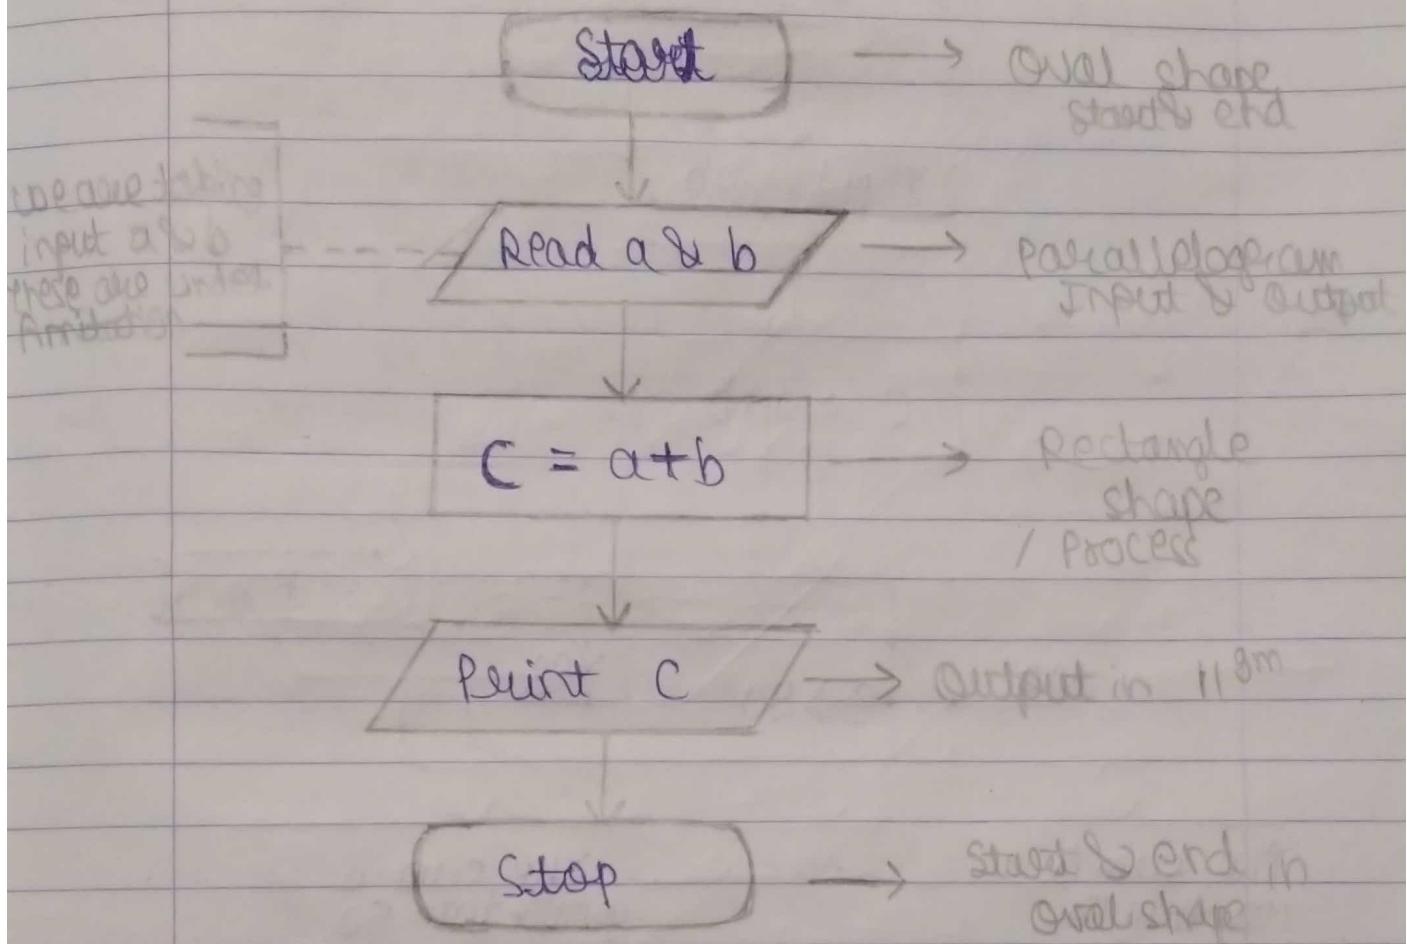

Page No. ....

Date.....

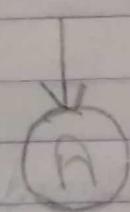

## Representation of Flowchart

- For addition of two number :

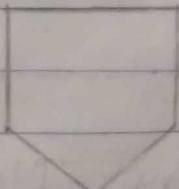

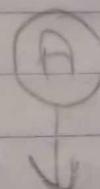

- One more important symbol is :

# Connectors ::

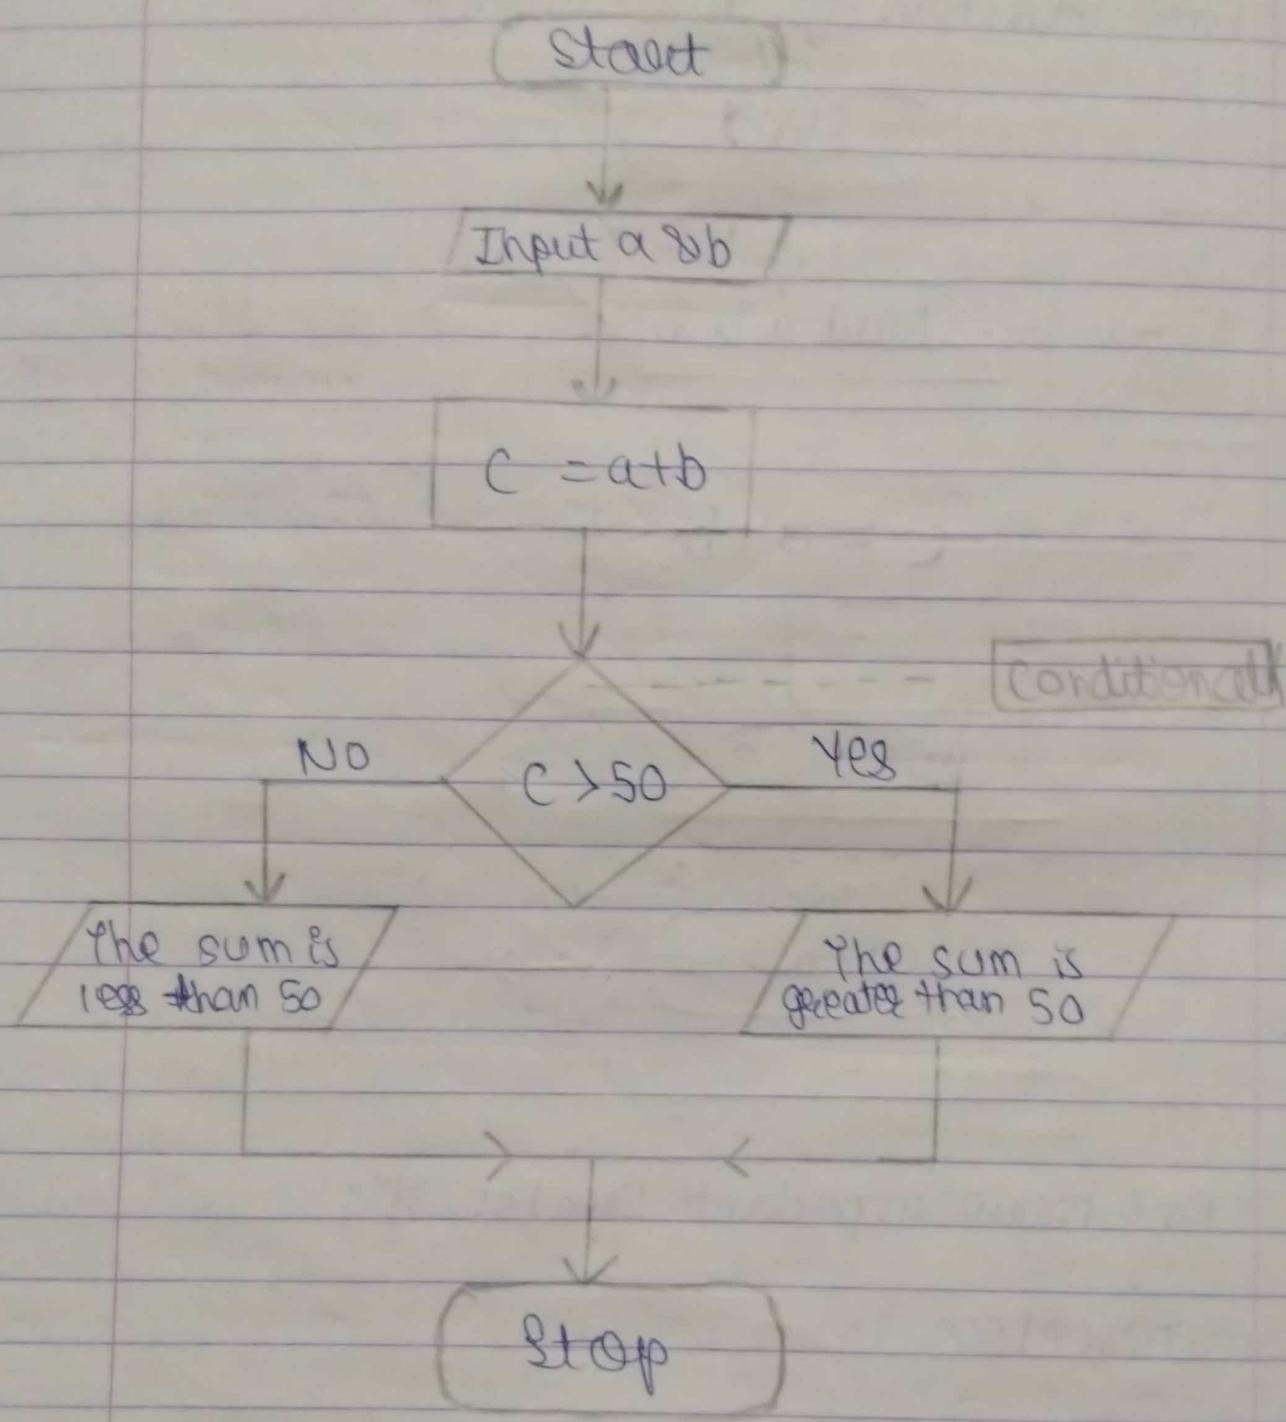

On page  
reference

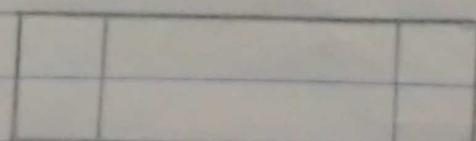

Off Page

# Start & end के लिए oval shape use एसी है।

# Decision making या conditional के लिए  
diamond / diamond shape use एसी है।

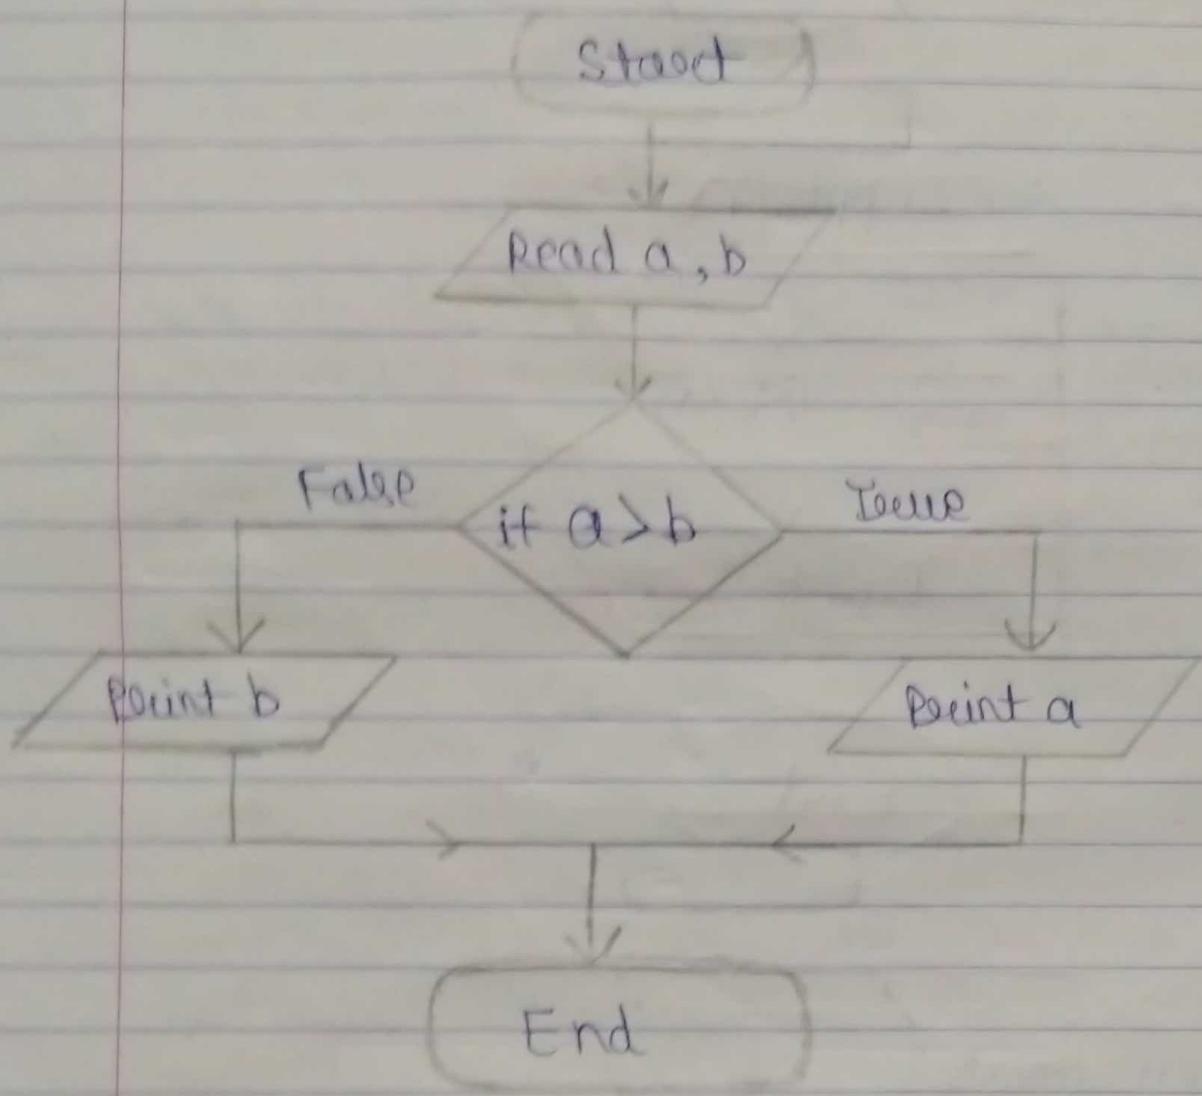

# FOR Looping Flowchart

Page No. \_\_\_\_\_  
Date \_\_\_\_\_

11.

Flowchart for making the program to find the greater no. b/w two numbers?

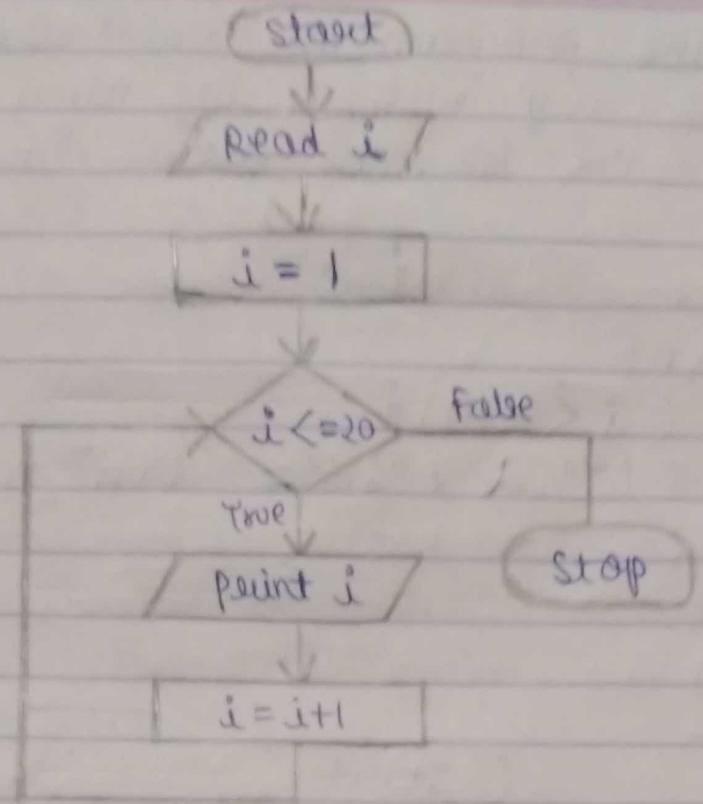

Here,

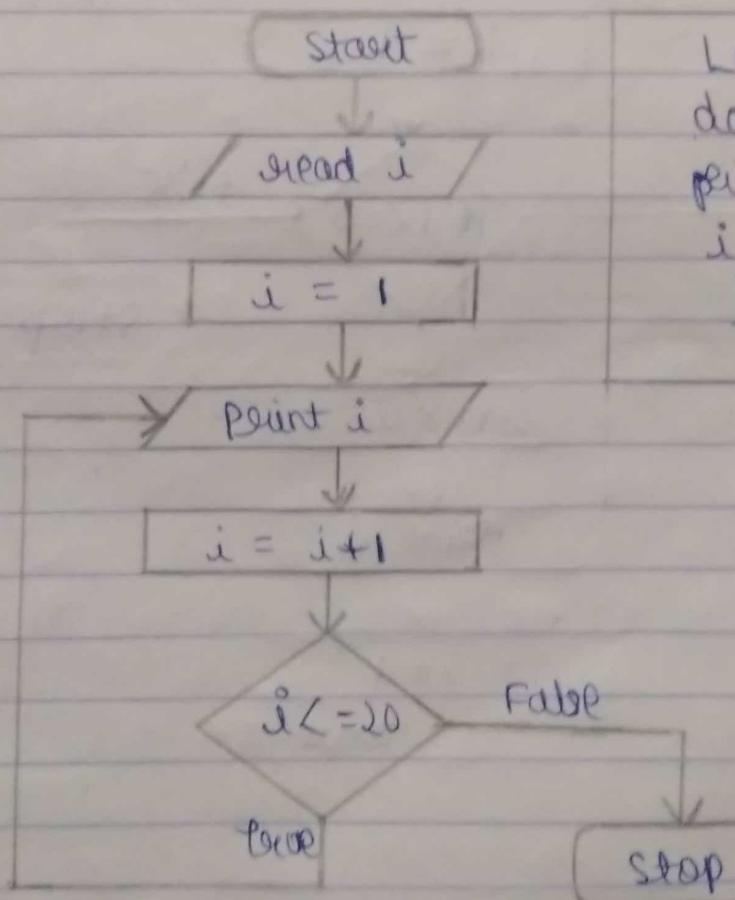

\* Now we will make the program to print the numbers from 1 - 20 by using while loop with the help of flowcharts.

```

logic = int i = 1
while (i <= 20) {
    printf("%d\n", i);
}
  
```

# Now same program in do while loop :

Logic :  
do {  
 print("%d\n", i);  
 i++;  
} while (i <= 20)

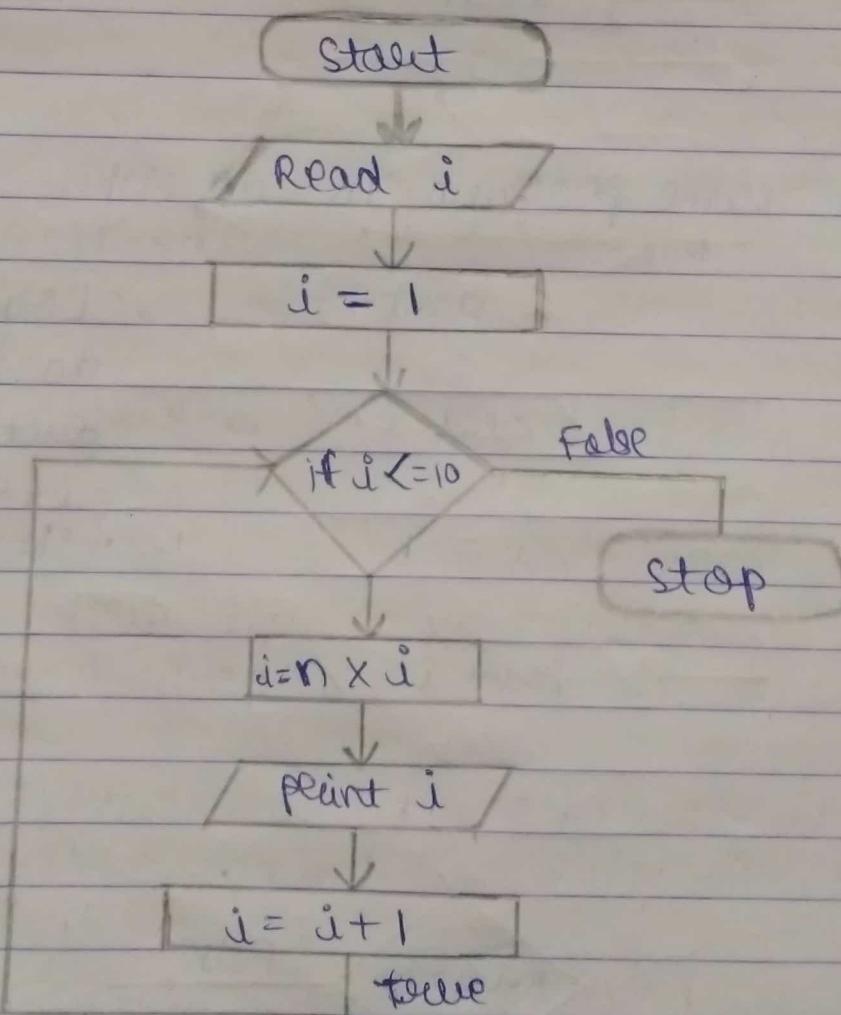

Ques → Now, write the program to write the multiplication table of any number by using while / for loop in the form of flow chart?

→ Logic :

```
int i=1, n;  
while (i <= 10) {  
    printf ("%d x %d = %d\n", n, i, n*i);  
    i++;  
}
```

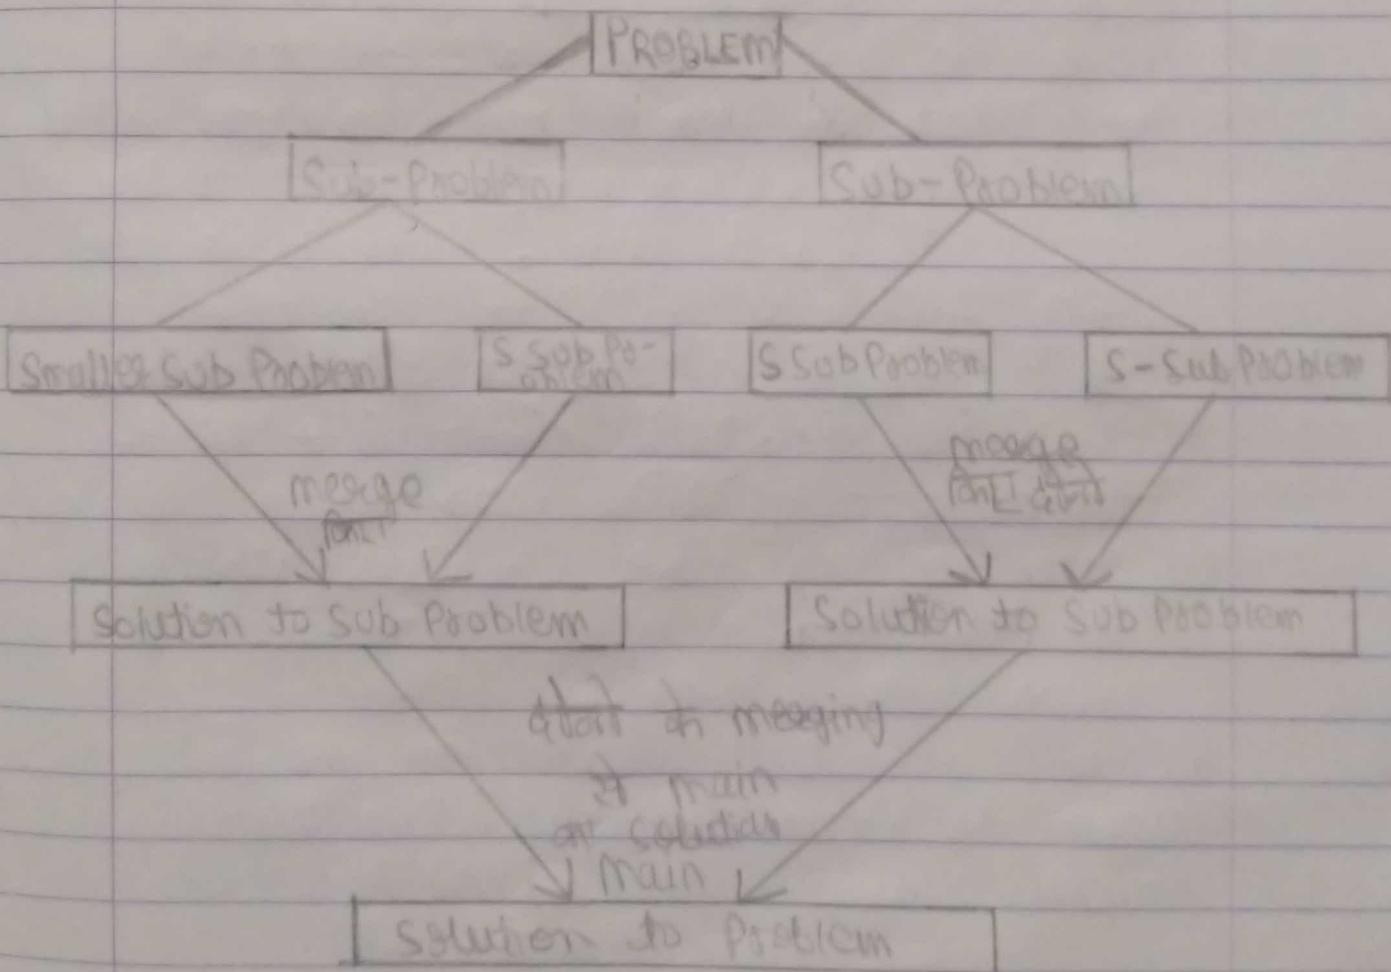

Start =

## \* Divide & Conquer :

- इसमें मैं simply हम एक को problem को होते - होते subproblems में divide करते हैं ताकि हम उस problem को easy way में से directly solve कर सकें।
- Divide & conquer is an algorithm design pattern which works by recursively breaking down a problem into sub-problems of similar type until these become simple enough to solve directly.

- \* What is divide & conquer?

Page No. ....  
Date. ....

- 1) Firstly we divide the problem into sub problems.
- 2) Then we solve the sub problems.
- 3) At last we merge the solutions to get the main problem's solution.

## Asymptotic notation

### \* Design & analysis of an algorithm :

Here there are many solutions of same program so we will implement only that one which takes least time & least memory. So here it is all depends upon time & memory. If that solution takes least time & least memory for  $S$  than that solution only get implemented than any other solution.

so simply here analysis means to read or absorb that in how much time the problem will solve & how much it take the memory to store.

### \* Asymptotic notation : Basically there were three asymptotic notation, first one is :

1) Big Oh notation ( $O$ ) = Here we are representing Big Oh as Capital ( $O$ ).

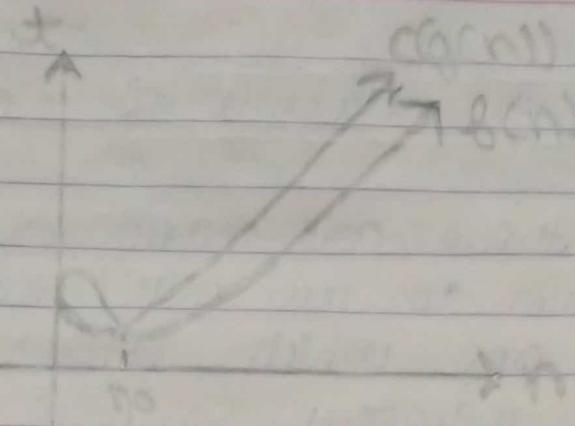

→ Big Oh notation is used to describe asymptotic upper bound, where upper bound means a curve representing the limit of a function.

We will understand it better by diagram:

Max time or maximum time

problem solve in a time taking

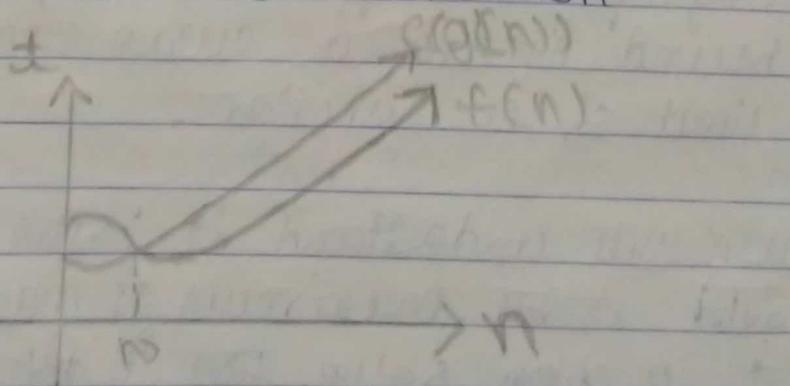

That's why worst case & current time taking

Hence,  $g(n)$  is the upper bound for  $f(n)$  so we can say that  $f(n)$  is upper bounded by  $g(n)$  & where  $c$  is constant.

- Here,  $n$  is the input size &  $t$  is the time growth. So, here the time complexity is there or the time increases which we named as  $f(n)$  where  $f$  is function &  $n$  is input size. Now here we will define some other function which we named as  $c(g(n))$  where when the  $f(n)$  is bounded with the other function  $c(g(n))$  & after some limit no, then in this case  $c(g(n))$  is always greater than the  $f(n)$  or  $f(n)$  is lesser than the  $c(g(n))$ .

Now all about its condition:

$$\begin{aligned}f(n) &\leq cg(n) \\cg(n) &\geq f(n) \\ \text{and } n &\geq n_0, c > 0, n \geq 1\end{aligned}$$

here why we take  $n$  as greater than or equal to one because an input should be atleast one.

so, here,  $f(n) = O(g(n))$ .  
also we can say that  $f(n)$  is smaller than  $g(n)$ .

lets take one question :

Q.  $f(n) = 3n+2, g(n) = n$

Soln)  $f(n) = O(g(n))$   
 $f(n) \leq c(g(n))$   
 $3n+2 \leq cn$   $\& \because \text{as } g(n) = n \}$

Now, we put the value of  $c$  as more than 3 when comparing with LHS : like  $c=4$

$$\begin{aligned}3n+2 &\leq 4n \\4n &\geq 3n+2 \\n &\geq 2\end{aligned}$$

if for  $f(n) = 3n+2, g(n) = n$ , so we prove the condition or satisfy the condition that?

$$f(n) = O(g(n))$$

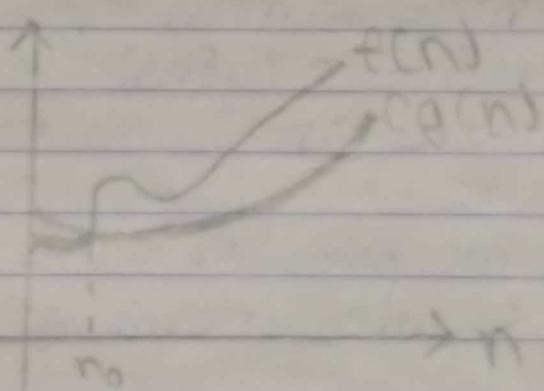

Here it means that  $g(n)$  is bounded the function  $f(n)$  so we can definitely say that any value greater than  $n$  like  $n^2, n^3, \dots$  are definitely going to bound  $f(n)$  in the case of upper bound.

② Big Omega = It is represented as the symbol  $\Omega$

→ Big Omega  $\Omega$  is used to describe the asymptotic lower bound.

When we describe it in graph it will be look like:

Big Omega ने किसी  
लेट से लेट लाई  
जाता है, किस से किस  
time वाला problem को  
solve किया किया  
that's why it best  
case कहता है।

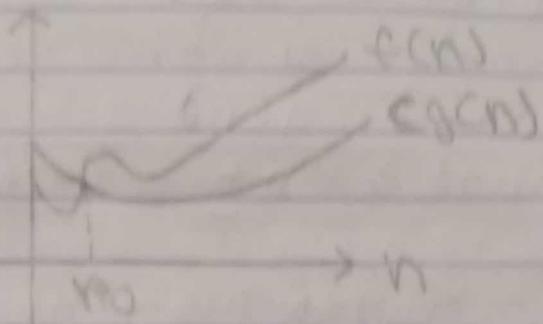

Here,  $g(n)$  is the lower bound for  $f(n)$  or we can say that  $f(n)$  is lower bounded by  $g(n)$ .

Now we can see that the time complexity named as  $f(n)$  then we have to define the lower bound for it then we will define some other function

which are named as  $c(g(n))$ .

Hence,  $f(n) \geq c(g(n))$  where,  
 $n \geq n_0 \& c > 0 \& n_0 \geq 1$

Same here why we take  $n_0 \geq 1$  because  
as it is input & input should have atleast  
one.

We will take one example:

∴  $f(n) = 3n+2$ ,  $g(n) = n$   
 $f(n) = \Omega g(n)$   
 $f(n) \geq c(g(n))$   
 $3n+2 \geq cn$

And,  $c > 0 \& n_0 \geq 1$  we will take  $c=1$

$$3n+2 \geq n$$

or  $3n+2 = \Omega n$

It simply means that  $f(n)$  is lower bounded by  $g(n)$ , let's take an another example for better understanding :-

Q.  $\Rightarrow f(n) = 3n+2$ ,  $g(n) = n^2$

$$f(n) = \Omega(n)$$

$$f(n) = \Omega n^2$$

$$3n+2 = \Omega n^2$$

$$3n+2 \geq cg(n)$$

$$3n+2 \geq Cn^2$$

i.e.  $g(n) = n^2$

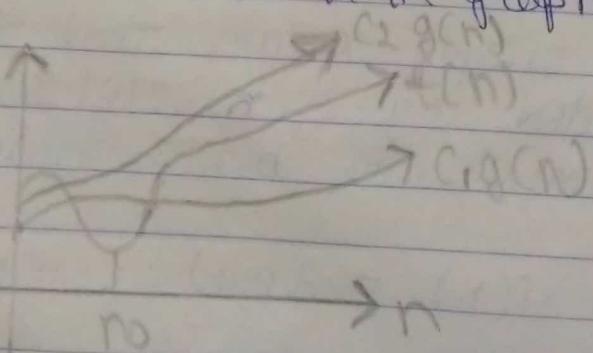

Here,  $3n+2$  means  $f(n)$  can't able to solve in this situation so we clearly say that any value more than  $n$  in the case of lower bound are not going to bound.

⇒ We can say that's for any value more than  $n$  are not going to bound but the value less than  $n$  like  $\log n$ ,  $\log(\log n)$  can bound easily in the case of lower bound.

③

**Big theta** : Big theta we can represented as  $\Theta$ .

In Big theta asymptotic notation we will define the function of both upper bound & lower bound. Now we will describe it in graphs

Big theta ( $\Theta$ ) is used when both the Big O( $O$ ) & Big Omega ( $\Omega$ ) are same)

Page No.

Date.....

We can easily identify it by seeing the diagram, as  $f(n)$  is lower bounded by  $c_1 g(n)$  &  $f(n)$  is upper bounded by  $c_2 g(n)$ , so the situation will be

$$\therefore f(n) = \Theta(g(n))$$

where,  $c_1 g(n) \leq f(n) \leq c_2 g(n)$ ,  
 $n \geq n_0 \& n_0 \geq 1$

$$\therefore \text{When } f(n) = 3n+2 \& g(n) = n$$
$$f(n) \leq c_2 g(n)$$
$$3n+2 \leq 4n, \& c=4 \}$$
$$4n \geq 3n+2$$
$$n \geq 2$$

which satisfies the condition for all the values of  $n_0 \geq 1$  in the case of upper bound

and when,  $f(n) \geq c_1 g(n)$

$$3n+2 \geq 1n \& c=1 \}$$
$$3n+2 \geq n$$

which satisfies the condition for all the values of  $n_0 \geq 1$  in the case of lower bound.

#### \* Short description :

- Big Oh ( $O$ ) is the worst case algorithm.
- Big Omega ( $\Omega$ ) is the best case algorithm.

Page No. ....  
Date. ....

- And  $O$  is the average case where  $O$  is used when both the  $O$  &  $S$  are same.

\* In divide & conquer we can say that,  
the given list is split into sublist to  
solve the problem.

Page No. \_\_\_\_\_

Date \_\_\_\_\_

## Merge Sort by divide & conquer

→ In this first step & second step we include :

1. First step is dividing the list into sublist then second step is to merging the sublist to getting one completed sorted list.

• We have to keep dividing the sublists until it is converted into one-one sublist / one-one elements.

• Merge sort is a recursive algorithm it means which continually splits a list in half or in two parts.

∴ We are taking one example : like we take one array list :

10	7	8	3	2	1
0	1	2	3	4	5

Now we have to divide the list until lower bound  $\leq$  upper bound.

Here is the formula to finding the midpoint as if we have to divide the list into sublist we have to firstly find its mid point which divides the given list.

$$= \text{lower bound} + \text{upper bound}$$

(i)

$$\begin{array}{cccccc} 10 & 7 & 8 & 3 & 2 & 1 \\ 0 & 1 & 2 & 3 & 4 & 5 \end{array}$$

$$\frac{1+0}{2} = \frac{0+1}{2} \\ = 2$$

(ii)

$$\begin{array}{cccccc} 10 & 7 & 8 & 3 & 2 & 1 \\ 0 & 1 & 2 & 3 & 4 & 5 \end{array}$$

$$\frac{1+0}{2} = \frac{0+1}{2} \\ = 1$$

$$\begin{array}{cccccc} 10 & 7 & 8 & 3 & 2 & 1 \\ 0 & 1 & 2 & 3 & 4 & 5 \end{array}$$

(iii)

$$\begin{array}{cccccc} 10 & 7 & 8 & 3 & 2 & 1 \\ 0 & 1 & 2 & 3 & 4 & 5 \end{array}$$

$$\frac{0+1}{2} = \frac{1+0}{2} \\ = 0$$

$$7 \ 10 \quad 2 \ 3$$

$$7 \ 8 \ 10 \quad 1 \ 2 \ 3$$

(iv)

$$\frac{3+5}{2} = \frac{8}{2} = 4$$

$$1 \ 2 \ 3 \ 7 \ 8 \ 10$$

This is the completed  
sorted list we get.

$$\frac{3+4}{2} = 3$$

Then

Merge sort II ex 8

like here one sublist already list is given, we have to solve this by using merge sort with the help of divide & conquer.

$$\begin{array}{cccccccccc} 15 & 5 & 24 & 8 & 1 & 3 & 16 & 10 & 20 \\ 0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \end{array}$$

Merge sort का Program किसका नहीं का?  
How to Write merge sort program?

→ Merge sort (A, lb, ub)

{ if (lb < ub)

{ mid = (lb + ub) / 2

mergeSort (A, lb, mid)

mergeSort (A, mid+1, ub)

merge (A, lb, mid, ub);

}

Recursive tree for how we merge.

Now, how can we solve the fig. 1 problem,  
we will give short summary type:

using method

ms (0, 8)

ms (0, 4)

ms (5, 8)

merge (0, 4, 8)

s (0, 2) ms (3, 4) ms (0, 2, 4)

ms (5, 6)

ms (7, 8)

merge (5, 6, 8)

ms (3, 3) ms (4, 4) merge (3, 3, 4)

ms (2, 2) merge (0, 1, 2)

ms (5, 5)

ms (6, 6)

merge (5, 5, 6)

s (0, 0) ms (1, 1) merge (0, 0, 1)

ms (7, 7)

ms (8, 8) merge (7, 7, 8)

Whole control will flow from (0, 0, 1)  
to the end & it will merge all the  
sublists into sorted form, result will be:

1	3	5	8	10	15	16	20	24
0	1	2	3	4	5	6	7	8

$$\frac{16+0}{2} = \frac{0+8}{2} = 4, \text{ and } \frac{0+4}{2} = 2$$

$$\frac{0+1}{2} = 0, \frac{16+0}{2} = \frac{0+2}{2} = 1, \frac{3+4}{2} = \frac{3}{2} = 1.5$$

Now we will see the full process :

0	1	2	3	4	5	6	7	8
15	5	24	8	1	3	16	10	20

0	1	2	3	4	5	6	7	8
15	5	24	8	1	3	16	10	20

0	1	2	3	4	3	16	10	20
15	5	24	8	1	3	16	10	20

0	1	2	8	1	3	16	10	20
15	5	24			3	16	10	20
0	1		1	8	3	10	16	20

5 15

5 15 24

1 5 8 15 24

1 3 5 8 10 15 16 20 24

This is our final completed sorted list which we getting by dividing into 5 the given list into sub list then by sort & merging we get final completed sorted list.

## IMP topic Quick Sort

- Quick sort is a divide & conquer algorithm. It works by selecting a 'pivot' element here pivot means the element which is chosen randomly by a chance from the given set, so here quick sort works by selecting a pivot element from the array & partitioning the other elements into two sub-arrays, according to if the it, the elements which are less than the pivot element should be shifted to left side of the pivot element & the elements which greater than the pivot element should be shifted to right side of the pivot element.
  - Quick sort is based on the idea that if an element is in sorted form all the element which is lesser than that element is on the left side & all the element which is greater than that element is after that on the right side of that element & that element is in sorted form
- ★ Now here we will solve some problems by quick sort method with the help of divide & conquer.
- |    |    |    |    |    |    |    |    |    |
|----|----|----|----|----|----|----|----|----|
|    | 0  | 1  | 2  | 3  | 4  | 5  | 6  | 7  |
| i) | 60 | 30 | 90 | 80 | 20 | 70 | 50 | 10 |
|    | 50 | 60 |    |    |    |    |    |    |

Let us take pivot = 60 so simple the all the elements which is less than the pivot will be shifted to left side of the pivot & all the elements which is greater than the pivot will be shifted right side of the pivot.

Step 1) First of all from the left side we have to increment till we get the value greater than pivot so here first we will increment to 30 which is not greater than 60 so we will increment again now on 50 which is greater than 60 then we will stop there, then from the right side we will decrease till the value get less than 60, first is 80 which is less than 60 so we will swap or interchange the digits 90 to 50.

60	30	50	80	20	70	90	00
----	----	----	----	----	----	----	----

Step 2) Now we will move to 80 which is greater than 60 from the left then from the right we will decrement to 70 but it is not less than 60 so again we will did decrement & move to 20, now stop their & swap both the 80 and 20.

60	30	50	20	80	70	90	00
----	----	----	----	----	----	----	----

Step 3)

Now here  $i$  is crossed to  $j$ ,  $i$  is greater than  $j$  so now we will not increment & decrement, now we will swap  $j$  with pivot element which is 60.

0	1	2	3	4	5	6	7
20	30	50	60	80	70	90	∞

$i$                            $j$                            $h$

this element is sorted

as before this all elements are lesser than it & after it all elements are greater than it.

Now we will divide it into two subparts first is off from 20, 30, 50 to next part is 80, 70, 90, why we don't take 60 because it is already sorted now we don't know either other than this other values are sorted or not so we have to sort all other values.

i	1	2	3	4	5	6	7
20	30	50	60	80	70	90	∞

Pivot = 20       $\underbrace{\hspace{1cm}}$        $\downarrow$        $\underbrace{\hspace{1cm}}$        $\rightarrow$  2nd sub-part

1st sub-part we don't have to sort it.      Pivot = 80

Step 4)

Now we have to solve 1<sup>st</sup> subpart as we will take pivot is 20 then we will increment to 30 as 30 is greater than 20 so we will stop there then from the right we will decrement to 50 as 50 is not less than 20 so we move to 30 which is also not less than 20 atlast we

come to 20 which is pivot so here it is classified that 1<sup>st</sup> subpart is also sorted.

20	30	50	60	80	70	90	∞
----	----	----	----	----	----	----	---

already sorted

Now we have to solve this 2<sup>nd</sup> subpart  
as it is not sorted.

Step 5) Now we will take pivot = 80 so we will increment to 70 which is not greater than 80 so we move towards 70 90 which is greater than 80 so we will stop there then from the right we will decrement to 70 which is less than 80 but here we don't swap both of these because these are cross each other so we will swap the j or decrement value with pivot 80 then we get complete sorted list.

0	1	2	3	4	5	6	7
20	30	50	60	70	80	90	∞

i      complete sorted list    h

Ans

Here, infinity is used as a end marker. so it is just used to end the list.

So, we get the completed sorted list by using quick sort which is based on divide & conquer.

simple algorithm for it:

Quick sort (l, h)

{

if ( $l < h$ )

{

$j = \text{partition}(l, h);$

Quick sort (l, j);

Quick sort (j+1, h);

}

}

- 2) Now with the help of another example we will understand it better.

0	1	2	3	4	5	6	7	8	9
10	16	8	12	15	6	3	9	5	00

$\downarrow \text{ i.e.}$                              $\downarrow \text{ - } h$

Pivot = 10

Solving this problem step by step:

Step 1) As we take the pivot be 10, now we have to firstly sort this pivot as this pivot will be sorted only when all the element which is greater than the pivot should be its right side & all the element which is less than pivot should be its left side. So, here first of all from right left side we will increment till we get the element greater than that pivot so we will increment to 16 which is greater than pivot so we

stop there then after that from left side we will decrement to 5 which is smaller than 10 so swap both of these or interchange both of these,

	0	1	2	3	4	5	6	7	8	9
A	10	5	8	12	15	6	3	9	16	00
	j	i++		j--						h

step 2)

Now we will move to 12 or index value 3 A[3] so here 12 is greater than 10 so we stop there then from right we will decrement to 9 which is less than 10 so we will swap / interchange both of these :

	0	1	2	3	4	5	6	7	8	9
A	10	5	8	9	15	6	3	12	16	00
	j		i++		j--					h

step 3)

Now from left we will move to increment from 9 to 15 as 15 is greater than 10 so we stop there now then from right we will decrement to 3 which is less than 10 so we swap / interchange both of these :

	0	1	2	3	4	5	6	7	8	9
A	10	5	8	9	3	6	15	12	16	00
	j		i++		j--					h

step 4) Now now, i is crossing to j which

means  $i$  is greater than  $j$  & then no increment & decrement which this type of case appears but after that  $i$  will be interchanged its position with the pivot value so in this case only pivot value will be sorted:

	0	1	2	3	4	5	6	7	8	9
A	6	5	8	3	13	10	15	12	16	00
	$i$					$j$			$k$	

10 is sorted

Here how can we say that 10 is sorted as the values before pivot (10) is less than it & after pivot all the elements is greater than pivot so 10 is sorted. Now we will sort all the elements by dividing into subpart 1 & subpart 2:

	0	1	2	3	4	5	6	7	8	9
A	6	5	8	9	3	10	15	12	16	00
	$\downarrow$	$\brace{Subpart\ 1}$	$\downarrow$	$\brace{Subpart\ 2}$						$Pivot = 15$

$pivot = 6$  Subpart 1      AS, 10 is already sorted so don't need to sort it again.

Step 5) Here now when solving subpart 1 we will take 6 as pivot:

	0	1	2	3	4	5	6	7	8	9
A	6	5	8	9	3	10	15	12	16	00
	$i$		$j+$	$j-$						

$pivot = 6$       Subpart 1       $k$

Step 6) ∵ In the subpart 1, from the left we will increment to 5 which is not greater than 6 so we move towards to 8 which is greater than 6 so we stop there, now from right we will decrement to 3 so swap both of these:

0	1	2	3	4	5	6	7	8	9
A	15	15	13	18	10	15	12	16	00

Step 7) ∵ Now, we will swap j with pivot as we can't increment & decrement more as they both were intersect each other so, j will interchanged with pivot which

0	1	2	3	4	5	6	7	8	9	
A	13	15	6	9	18	10	15	12	16	00

↓      ↓      ↓  
sorted    subpart 2    subpart 3

As, 10 is already sorted but with the help of 10 we will sort 9 & 8 that's why we will take help of it:

0	1	2	3	4	5	6	7	8	9
13	15	6	9	8	10	15	12	16	00

↓      ↓      ↓  
sorted    pivot    subpart 3  
already    j      subpart 2

Step 8) Here in subpart 2 now we will increment to 8 as we take pivot 9 so 8 is not greater than 9 so we move toward to 10 & we also stop then from eight we will decrement to 8 which less than 9 then we swap both 9 & 8 :

0	1	2	3	4	5	6	7	8	9
3	5	6	8	9	10	15	12	16	00

↓ sorted already      ↓ subpart 3      pivot = 15

Now here from index 0 to 5, all the elements are sorted then we will solve the subpart 2 here we taking pivot = 15 :

0	1	2	3	4	5	6	7	8	9
3	5	6	8	9	10	15	12	16	00

↓ j-- i++      ↓ subpart 3

Step 9) As, in subpart 3 i is closed to j so we don't increment or decrement it, but we will swap j with pivot value 15 so we get completed sort list :

0	1	2	3	4	5	6	7	8	9
3	5	6	8	9	10	12	15	16	00

Ans

thus : here all the elements are

completely get sorted.

3. Some algorithm for it:

quick sort ( $l, h$ )

{

if ( $l < h$ )

{

$j = \text{position } (l, h);$

quick sort ( $l, j$ );

quick sort ( $j+1, h$ );

{

{

$\therefore l = \text{lower},$

$h = \text{higher},$

$j = \text{pivot or the point where array}$   
 $\text{we divided two subparts}$

3) You have given the array sort this  
with the help of quick sort by using  
divide & conquer.

0	1	2	3	4	5	6	7
10	15	11	12	9	16	11	00

Here the given array is unsorted so we  
will sort this step by step method:

	0	1	2	3	4	5	6	7
A	10	15	1	2	9	16	11	00

i      j++      ↓      h

pivot = 10

step1) Here we are taking pivot = 10 so first of all from the left we will increment till the element greater than pivot so here 15 is greater than 10 so we will stop there then from right we will decrement as 11 & 16 both are not less than 10 so we will decrement again, now 9 is less than 10 so we stop here & swap both the 15 & 9;

	0	1	2	3	4	5	6	7
A	10	9	1	2	15	16	11	00

i      j++      ↓      h

step2 Now here i is crossed the j so we can't increment or decrement anymore in this case we will swap j with the pivot value.

	0	1	2	3	4	5	6	7
A	2	9	1	10	15	16	11	00

i      ↓      h

10 is sorted here;

Now we know that 10 is sorted.

- Is all the elements which is less than 10 is on its left side & all the elements which is greater than 10 is on its right side?

	0	1	2	3	4	5	6	7
A	12	9	11	10	15	16	14	00

subpart1      subpart2

Now we will solve subpart1 firstly  
as how it works :

	0	1	2	3	4	5	6	7
A	12	9	11	10	15	16	14	00

Pivot = 2

steps As, here we are taking pivot = 2 so we will increment pivot to 9 here 9 is greater than 2 so it stops there then from left from index A[2] so it will decrement to 1 & then swap 9 & 1:

	0	1	2	3	4	5	6	7
A	12	11	9	10	15	16	14	00

i    j = i++

h

step 2 Now control moves towards from left that increment will to 9 where 9 is greater than 2 so we stop there then from right decrement to 1 but here i is crossed with j so no increment & decrement will possible, so in this

case we will swap  $j$  with pivot value & we get:

0	1	2	3	4	5	6	7
A	1	2	9	10	15	16	11 $\infty$

$i$   $j$   $j+1$   $h$   $\downarrow$

completely sorted | subpart 2

pivot = 15

steps) Here now in subpart 2, from left we will increment to 16 as it is greater than the pivot value 15 so we stop here then from right 11 is less than 15 so we swap both 16 & 11 :

0	1	2	3	4	5	6	7
A	1	2	9	10	15	11	16 $\infty$

$i$   $j$   $j+1$   $h$

pivot = 15

steps) Here  $i$  is crossed  $j$  so increment & decrement is not possible so in this case we will swap  $j$  with pivot value & then we will get complete sorted list:

0	1	2	3	4	5	6	7
A	1	2	9	10	11	15	16 $\infty$

$i$   $j$   $h$   $\uparrow$   $\infty$

Here is the complete sorted list.

Algorithm: (Same as before):

```

    quick sort (l, h) {
        if (l < h) {
            {
                j = partition (l, h);
                quick sort (l, j);
                quick sort (j+1, h);
            }
        }
    }
}

```

wheel, I = lower size

h = higher size

$i =$  pivot or the point where we divide 2 subparts.

Here another example:

0	1	2	3	4	5	6	7	8
34	26	1	45	18	78	12	89	21

$$\text{Pivot} = 34$$

1

b

Step 1) Here is the given array list in which we took 34 as an pivot element & firstly we have to select pivot element which means pivot element is sort only when all the elements lesser than pivot should be shifted on its left & all elements greater than pivot should be shifted on its right.

0	1	2	3	4	5	6	7	8
34	26	1	35	18	78	12	83	32

Step 2) Here firstly we will increment  $i$  till we get the element greater than pivot so here first from the left we will increment to 26 but 26 is not greater than pivot element again we will increment to 1 also 1 is not greater than pivot element so again we will increment to 45 which is greater than 34 so we will stop there then from the right we decrement to 27 which is less than the pivot element so we swap both of the elements 45 & 27:

0	1	2	3	4	5	6	7	8	9
34	26	1	27	18	78	12	89	45	27
$i$			$j = i + 1$					$h$	

Step 3) Here, now from the we will move to 18 which is not greater than 34 so again we will increment to 78 which is greater than 34 so we stop there, now from the right we will do decrement to 89 but 89 is not less than 34 so again decrement to 12 which is less than 34, so now we will swap both of the element 78 & 12:

0	1	2	3	4	5	6	7	8	9
34	26	1	27	18	12	78	89	45	
$i$				$j = i + 1$				$h$	

Step 4) As  $i$  crossed  $j$  so we stop increment & decrement as the value of  $i$  is greater than  $j$  so in this case we will swap  $j$  with

the pivot value?

0	1	2	3	4	5	6	7	8
12	26	1	29	18	34	78	89	45

Pivot = 12

Subpart 1 : As the element is less than pivot

Subpart 2 :

Step 5) Now we will solve firstly subpart 1 & hence we took pivot as 12:

0	1	2	3	4	5	6	7	8
12	26	1	29	18	34	78	89	45
1	26	29	18	34	78	89	45	

Step 6) As from the left we will increment to 26 which is greater than 12 so we stop there, now from the right we will decrement to 18 which is not less than 12 so again move to 27 which is also not less than 27 again we will decrement to 1 which is less than 12 so we swap those

0	1	2	3	4	5	6	7	8
12	1	26	27	18	34	78	89	45
1	26	27	18	34	78	89	45	

Step 7) Here, i crossed j so in this case we will swap j with the pivot element & we get :

0	1	2	3	4	5	6	7	8
1	12	26	27	18	34	78	89	45

completely sorted subpart 2

Step 8: Now we will solve subpart 2 from index value 2 to 4 as 34 is already sorted so we doesn't involve this :

0	1	2	3	4	5	6	7	8
1	12	26	27	18	34	78	89	45

st=26 sorted subpart 2 subpart 3

Step 9: Here in subpart 2, we will increment to 27 from the left & from the right decrement to 18 then swap both of these :

0	1	2	3	4	5	6	7	8
1	12	26	18	27	34	78	89	45

sorted subpart 2 subpart 3

Step 10: Here i crossed j so we will swap j with the pivot element ?

0	1	2	3	4	5	6	7	8
1	12	18	26	27	34	78	89	45

we get completed sorted subpart 3

pivot = 78

Step

step11) Now here in the subpart 3, we take 78 as pivot & will increment ~~to 89~~  
 & stop here now from the right side  
 decrement to 43 which is less than pivot  
 so swap both of these ?

0	1	2	3	4	5	6	7	8
14	12	18	26	27	34	72	43	89
								J - with

step12) As .i is crossed j so we will swap j with pivot element 78 in the subpart 3 so we will get completely sorted list.

0	1	2	3	4	5	6	7	8
14	12	18	26	27	34	72	43	89
								b

Ans

As, here all the elements in the sorted form :

Now algorithm:

Quick sort (l, h);  
 if (l < h) {

j = position (l, h);

Quick sort (l, j);

Quick sort (j+1, h);

}

}

$$\text{mid} = \frac{lb+ub}{2} \rightarrow \frac{0+7}{2} = 3, \text{ (i) } 0+3 = 1$$

$$(\text{ii}) \cancel{0+1} = 0 \quad (\text{iii}) \cancel{0+1} = 5$$

Here are some questions:

**[IMP RGPA]**

\* H.W.  
Ans)

You have given the array, solve this  
array by using merge sort:

1	2	3	4	5	6	7		
142	543	123	65	453	879	572	434	-- 1st Part

0	1	2	3	4	5	6	7	
142	543	123	65	453	879	572	434	-- 2nd Part

0	1	2	3	4	5	6	7	
142	543	123	65	453	879	572	434	-- 3rd Part

142	543	123	65	453	879	572	434	-- 4th
142	543	65	123	453	879	434	572	-- 5th

65	123	142	543	434	453	572	879	-- 6th
----	-----	-----	-----	-----	-----	-----	-----	--------

→ [We merge here]

65	123	142	434	453	543	572	879
----	-----	-----	-----	-----	-----	-----	-----

Algorithm:

Here we get the completed sorted list : Algorithm for merge sort:

merge sort (A, lb, ub) {

if (lb < ub) {

mid point =  $lb + ub / 2$

merge sort (A, lb, mid point)

merge sort (A, mid point + 1, ub)

merge (A, lb, mid point, ub)

JMP

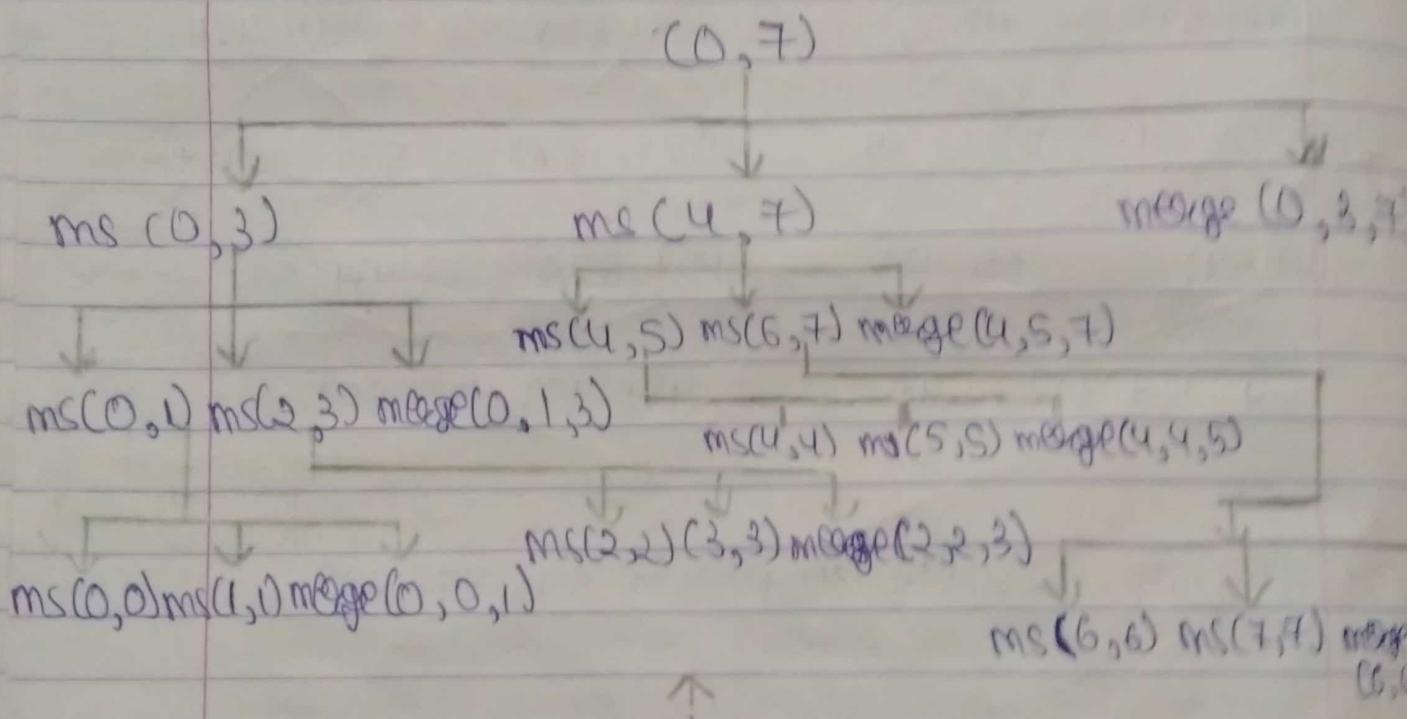

After merging the elements we get that element in the sorted form:

where,  $lb = \text{lower bound which is always starts from } 0, \text{ means index value be } 0.$

$ub = \text{upper bound which is the largest index value of the array.}$

\* Recursive tree for merging / How merging could be done:

this is the full recursive tree to help to merge the elements after dividing the element.

Similarly it is the method to merge the subparts.

Ques) You have given the array, solve the problem by using Quick sort:

0	1	2	3	4	5	6	7	8	9	10	11
44	33	11	55	77	90	40	60	99	22	88	66

pivot = 44

Step 1) Here we take pivot = 44 so what we have to do is that we have to sort 44 as the elements which is less than pivot should be shifted to its left & the elements which is greater than pivot should be shifted to its right. Now firstly we will increment towards 55 as this element only after 44 is greater so we will stop there from the right we will decrement towards 22 which is less than 44:

0	1	2	3	4	5	6	7	8	9	10	11
44	33	11	55	77	90	40	60	99	22	88	66

i++

j--

h

Step 2) Here when comparing with pivot, 33 & 11 both are not greater from 44 so we will increment to 55 from the left then from the right as 66 & 88 are not less than 44 so we move to 22 then swap both of the elements:

0	1	2	3	4	5	6	7	8	9	10	11
44	33	11	22	77	90	40	60	99	55	88	66

i++

j--

h

Step 3) Now we move to 77 which is greater than pivot so we stop there now from the right we decrement to 40 which is less than pivot so we swap both i & j;

0	1	2	3	4	5	6	7	8	9	10	11
44	33	11	22	40	90	77	60	99	55	88	66

j-- i++

Step 4) As i crossed j so we don't increment & decrement now, in this case we swap the value of j with the pivot value:

0	1	2	3	4	5	6	7	8	9	10	11
40	33	11	22	44	90	77	60	99	55	88	66

Subpart 1

Subpart 2

This value  
is got sorted

∴ As we can see that 44 is only get selected as the values greater than 44 is on its right side & the values less than 44 is on its left side, so we can clearly say that 44 is get sorted.

∴ Now take subpart 1 & here we take its pivot value is 33 then 33 either we increment to 40 from right & decrement to 22 from left;

0	1	2	3	4	5	6	7	8	9	10	11
40	33	11	22	44	90	77	60	99	55	88	66

i++

j--

steps) Now swap both i & j :

0	1	2	3	4	5	6	7	8	9	10	11
22	33	11	40	44	90	77	60	99	55	88	66

j = i++

steps) As we increment i to 40 which is greater than 33 (pivot value). As i crossed j so in this case j is swap with pivot value :

0	1	2	3	4	5	6	7	8	9	10	11
22	11	33	40	44	90	77	60	99	55	88	66

j = i++

Again let we take pivot = 22, here in this case i crossed j so, j is swap with pivot value (here 11 replaced with 22) :

0	1	2	3	4	5	6	7	8	9	10	11
11	22	33	40	44	90	77	60	99	55	88	66

this part is get sorted

subpart 2

(q7) ∵ In subpart 2 we will take 90 as pivot & we will increment at 99 which is greater than 90 from left & from right we will decrement to 66 which is less than 90 ∵

0	1	2	3	4	5	6	7	8	9	10	11
11	22	33	40	44	90	77	60	99	55	88	66

i++

j--

Step 8): Now we will swap the values of i & j:

0	1	2	3	4	5	6	7	8	9	10	11
11	22	33	40	44	90	77	60	66	55	88	99

j-- i++

Step 9): As, i crossed j so in this case increment & decrement is not possible as i is larger than j, so in this case we swap the value of j with pivot:

0	1	2	3	4	5	6	7	8	9	10	11
11	22	33	40	44	88	77	60	66	55	90	99

j-- i++

Step 10): Now we take pivot as 88 then here j is crossed j so in this case we will swap j with pivot value.

0	1	2	3	4	5	6	7	8	9	10	11
11	22	33	40	44	55	77	60	66	88	90	99

j-- i++

Swapped now we have to solve pivot = 90  
this subpart 3

Step 11): Here, we took pivot 90 & then increment towards 99 & decrement towards 90, then swap j with pivot 90 so we get same result it means 90, 99 both are sort?

0	1	2	3	4	5	6	7	8	9	10	11
11	22	33	40	44	55	77	60	66	88	90	99

j-- i++

Swapped Pivot = 55 Subpart 4

Swapped

Step(12):

In Subpart 4, pivot = 55 then increment to 77 & decrement to 55 so in this case i crossed j so we swap pivot value with j means 55 is placed with 55, it means 55 is sorted:

0	1	2	3	4	5	6	7	8	9	10	11
11	22	33	40	44	55	77	60	66	88	90	99

i++ j--

this is completely sorted

pivot = 60

sorted

Step(13):

Here we take index 6 & index 7 so we took pivot 60 so we increment to 77 & decrement to 60 then swap both the values of i & j:

0	1	2	3	4	5	6	7	8	9	10	11
11	22	33	40	44	55	60	77	66	88	90	99

sorted

60 also

get sorted

pivot = 77

subpart 4

Step(14):

Here in Subpart 4 we took pivot there are two elements only so increment to 77 & decrement to 66 then swap both of these & we get completed sorted list:

0	1	2	3	4	5	6	7	8	9	10	11
11	22	33	40	44	55	60	66	77	88	90	99

Ans

completed sorted list

Algorithm :-

```
quicksort (l, h) {
    if (l < h) {
        j = partition (l, h)
        quicksort (l, j)
        quicksort (j+1, h)
    }
}
```

## Recursion

→ In this a function called itself & in recursion a single part is divided into subparts to solve the problem easily.

One of the most imp. topic of recursion is Tower of Hanoi.

Here are some rules for solving the problem of Tower of Hanoi:

- i) Only one disk can be moved at a time. (एक बार एक ही डिस्क मोव एकही है)
- ii) In simple language, you can move the upper disk from the any pillar & also only place on the top of the pillar.
- iii) Each move consists of taking the upper disk from one of the stacks & placing it on top of another stack. In other words, a disk can only be moved if it is the uppermost disk on on a stack.
- iv) No larger disk can be placed on top of the smaller disk. (सकम्भ नीट अस्ति & फल उसके लिए उपर उससे small रहेगा)

Solution for disks :

## Solution for single disc :

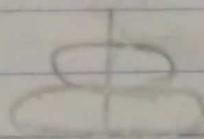

∴

There were three pillars, A, B & C  
here A is source pillar, B is auxiliary  
(Helping) pillar & C is destination pillar.  
when we talk about single disk, we  
can directly move a disk from A to C  
but if we have without taking help  
from the B pillar but if A had  
multiple no. of disk then we can't  
move directly from A to C disc that  
time we will take help from pillar B.

Here, we completely moved the disc  
from A to C.

## Now, solution for 2 disc :

A

B

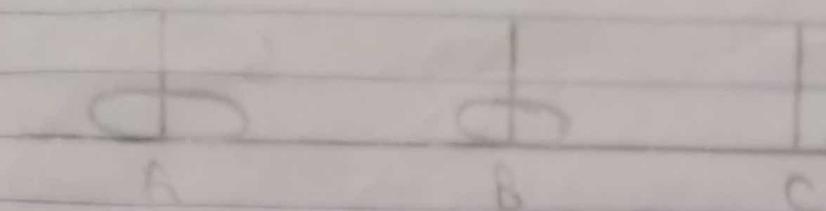

C

- ∴
- Move a disc from A to B using C
  - Then move a disc from A to C using B

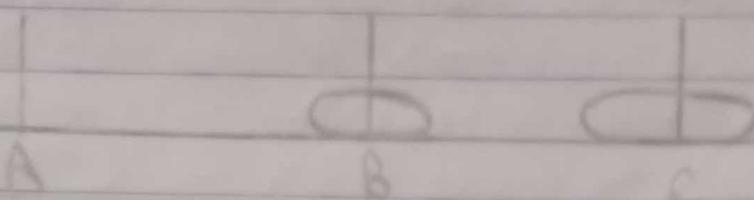

o Atlast move a disc from B to C :

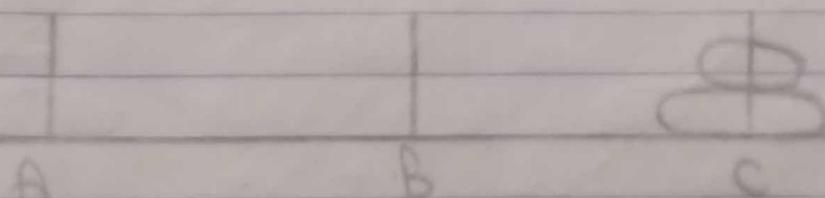

ii) move a disc from A to B :

iii) move a disc from A to C :

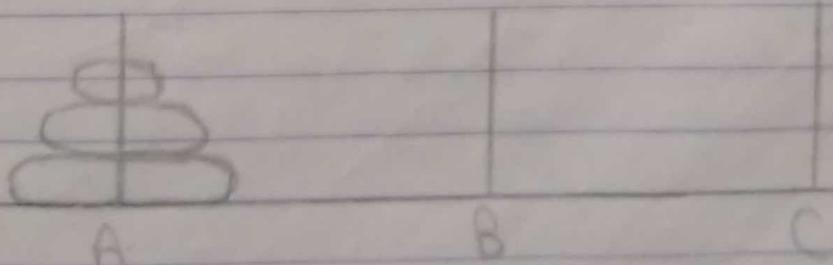

iii) move a disc from B to C for getting the final result :

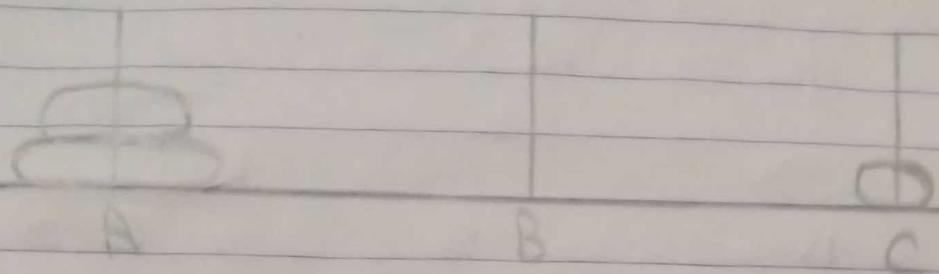

Here we completely moved all the disc from source to destination pillar.

\* Now solution for 3 disc :

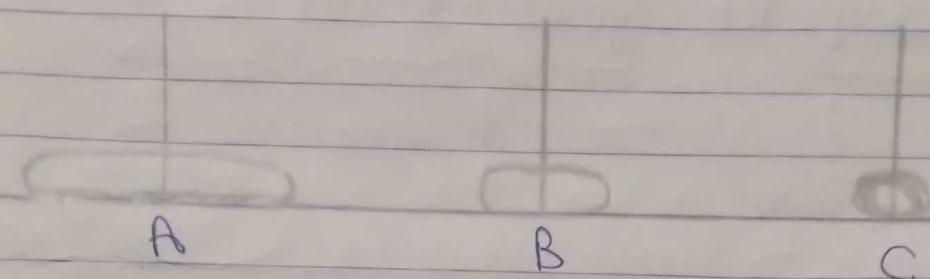

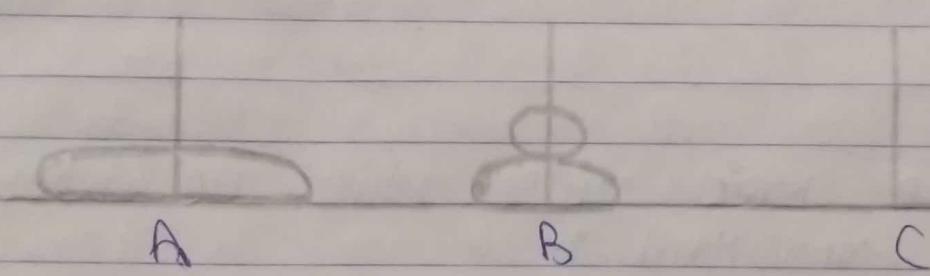

Step1) Now move a disc from A to C :

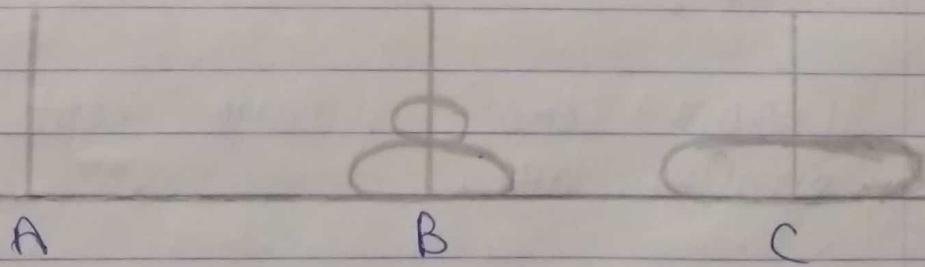

Step2) Move a disc from A to B :

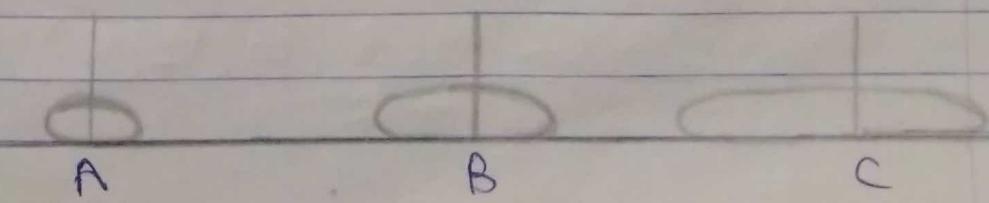

Step3) Move a disc from C to B :

Step4) Now, move a disc from A to C :

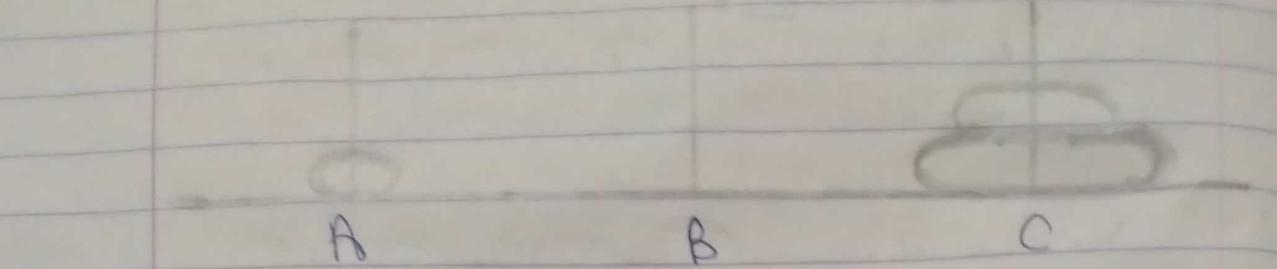

Step5) Now, move a disc from B to A :

step 6) move a disc from B to C

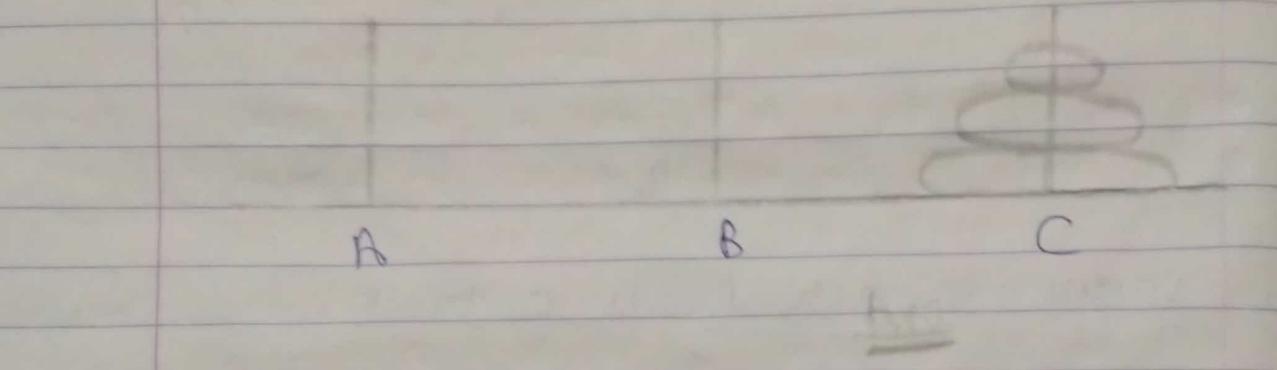

A

B

C

step 7) Move a disc from A to C after getting the final result;

A

B

C

\* some basic rules which we have to understand :

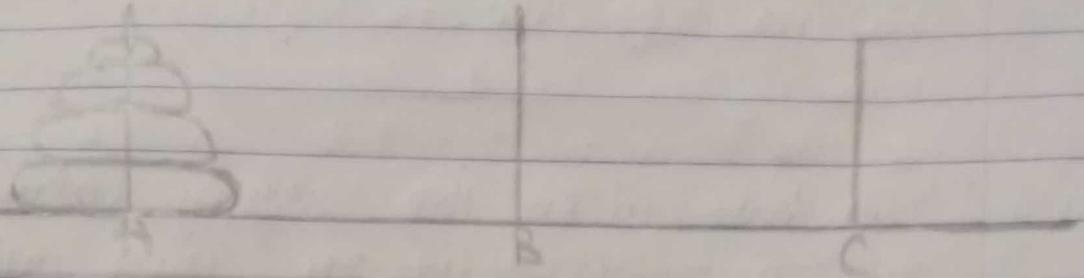

i) We can move only one disc at a time.

ii) Larger disc always kept after smaller disc.

iii) -The disc which is on the top most can only move & placed.

\* solution for  $n$  disk :

- i) Move  $n-1$  disk from A to B using C.
- ii) Move a disk from A to C.
- iii) Move  $n-1$  disk from B to C using A.

∴ Here if  $n=4$ , by using upper diagram  
if  $n=4$  then firstly we will move  
3 (4-1) disk to B then we move a  
disk from A to C, atlast we move  
that 3 (4-1) disk to C for getting  
completely final result :

- some rules for  $n$  no. of disks:
- i) Move the top  $n-1$  disks from source to destination auxiliary pillar.
- ii) Move the  $n^{\text{th}}$  disk from source to destination pillar.
- iii) Move the  $n-1$  disk from auxiliary pillar to destination pillar.
- iv) Repeating the top  $n-1$  disks from source to auxiliary pillar can again be thought as a fresh problem & can be solved in the same manner.

- steps will be  $\lceil \log_2 n \rceil$  where  $n$  is no. of disk.

Ques 3 You have given the array, solve the problem of sort it by using quick sort

0	1	3	2	4	5	6	7	8
10	4	12	2	14	8	16	6	18

part = 10

Step 1) We have taken the pivot = 10 so we have to sort the pivot as like the elements which is less than the pivot should be shifted to its left & the elements which is greater than the pivot should be shifted to its right.  
So, we will increment towards 12 from the left as it is greater than the pivot & from the right we will decrement to 6 as it is less than 10 so we will point it as  $j^-$ :

0	1	2	3	4	5	6	7	8
10	4	12	2	14	8	16	6	18

i++                          j--

Step 2) Now swap both i &  $j^-$

0	1	2	3	4	5	6	7	8
10	4	6	2	14	8	16	12	18

i++                  j--

Step 3: Now increment ( $i$ ) & decrement ( $j$ ) to 8 then swap both of  $i$  &  $j$  which we incre. & decre.

0	1	2	3	4	5	6	7	8
10	4	6	2	8	14	16	12	18

$j = i++$

Step 4: Now, we will move towards for finding next  $i$  &  $j$ , so we will find here that  $i$  crossed  $j$  so in this case we swap  $j$  with the pivot value:

0	1	2	3	4	5	6	7	8
8	4	6	2	10	14	16	12	18

As 10 is selected now

Subpart 1      ↓      Subpart 2

So Here, as 10 is selected all the elements which is less than it is on its left side & all the elements which is greater than it is on its right side. Now we will solve subpart 1 where we take 4 as pivot:

0	1	2	3	4	5	6	7	8
8	4	6	2	10	14	16	12	18

pivot=4       $i++$        $j-$

Step 5): As we are taken pivot = 4 so we will increment towards 8 which is greater than 4 from left so we will stop there & then from right decrement to 2 which is less than pivot value, so we will swap both i & j (decre.).

0	1	2	3	4	5	6	7	8
2	4	6	8	10	14	16	12	18

sorted part                    subpart 2

pivot = 10

∴ Now in Subpart 2 we will take pivot = 10 & will increment to 16 from left & then decrement to 12 from right.

0	1	2	3	4	5	6	7	8
2	4	6	8	10	14	16	12	18

i++      j--

Step 6): Now swap both i & j :

0	1	2	3	4	5	6	7	8
2	4	6	8	10	14	12	16	18

$i \leftarrow j - i + j$   
pivot value

Step 6): As here now i crossed j so in this case we will swap j with its pivot value & then we get complete sorted list.

0	1	2	3	4	5	6	7	8
2	4	6	8	10	12	14	16	18

1

n

Ans

- Algorithm :

```
Quick sort (l, h) {  
    if (l < h) {  
        j = pivot/position (l, h)  
        Quick sort (l, j)  
        Quick sort (j+1, h)  
    }  
}
```

Remaining Tower of Hanoi

- Tearing for 3 discs

- As for n no. of disk:

- If we have three towers A is source tower, B is auxiliary tower & C is destination tower. So for n no. of tower:

- 1) Move n-1 disk from A to B.
- 2) Move a ~~disk~~ from (nth) disk from A to C.
- 3) Move n-1 disk from B to C.

- The program for n disk:

```
void TOH (int n, int A, int B, int C)  
{  
    if (n > 0)  
    {  
        TOH (n-1, A, C, B);  
    }  
}
```

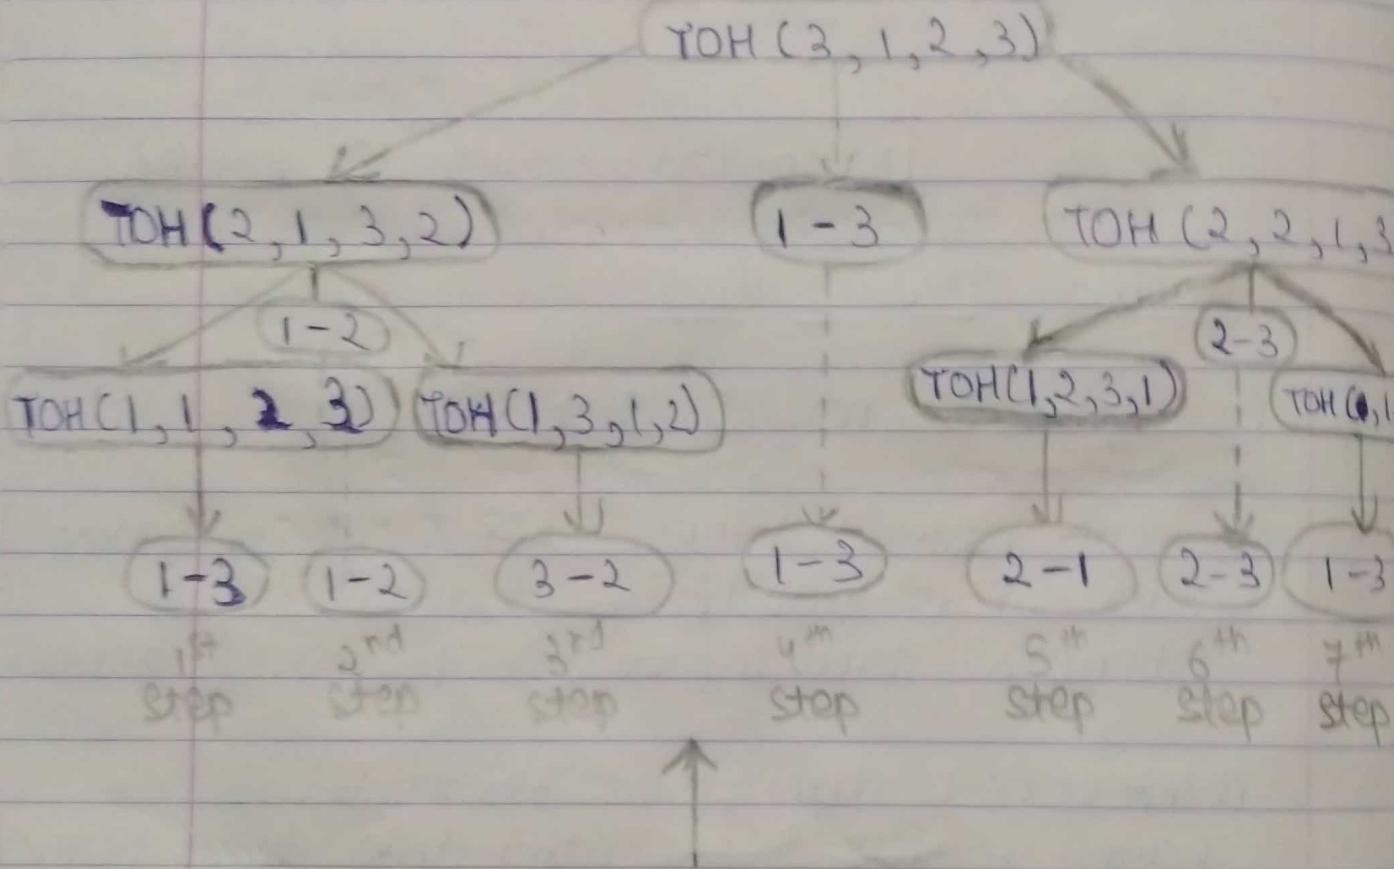

move  $n-1$  disc from A to B  
move  $n^{\text{th}}$  disc from A to C  
move  $n-1$  disc from B to C

```
printf("Move a disc from %d  
to %d", A, C);  
TOH(n-1, B, A, C);
```

}  
}

### Leaving for 3 Disc

This is how we can do transferring of disc from source to destination.

∴ For 4, 5 & any disc we can transfer easily with this method.

## Fibonacci Series

Another example of recursion is Fibonacci series.

Fibonacci series :- इसके पहले के 2 no. का sum हमें third term के मिलता है तो उसी जैसी series आगे बढ़ती है तो second term first term से connect हो जाती है & previous 2 term का sum second term से जा जाता है,

Like there is a series :-

0, 1, 1, 2, 3, 5, 8, ....

next term = first + second

first term = second

second term = next term

Write a program to print fibonacci series.

```
#include <stdio.h>
```

```
int main()
```

```
int first = 0, second = 1, num, i, next;
```

```
printf ("Enter the number: ");
```

```
scanf ("%d", &num);
```

```
printf ("The %d numbers in fibonacci series  
is: ", num);
```

```
for (i = 0; i < num; i++) {
```

```
if (i <= 1) {
```

```
next = i;
```

```
}
```

else if

next = first + second;

first = second;

second = next;

}

printf("%d", next);

}

return 0;

}

Input:

Enter the number : 5

Output:

The 5 numbers in Fibonacci series is :

0 1 1 2 3
